The Position of the Uterus in the Living: Exhibit of roentgenographic and photographic studies of living adult females, both normal and with varying degrees of prolapse, made after adequate visualization of the uterus; by reflected light the photograph only is apparent, while by transillumination the uterine position and the skeletal structures are imposed on the photograph of the body form.

WILLIAM H. VOGT, WILLIAM C. STUDE, PAUL FLETCHER and ROY V. BOEDEKER, St. Louis University School of Medicine, St. Louis:

Aspects of Obstetric Practice in St. Louis and in Missouri: Exhibit showing public health aspect and postgraduate instruction to the physician in the practice of obstetrics; analgesia in obstetric practice; cesarean section in a series of selected hospitals in St. Louis.

SAMUEL L. SIEGLER, Brooklyn:

Artificial Ovulation in the Human Being with the Hormone of Pregnant Mare's Serum and Its Clinical Application: Exhibit depicting artificial ovulation in the rabbit, monkey and human being with the hormone of pregnant mare's serum and its clinical application, in the human being in amenorrhea and sterility and anovulatory menstruation, functional bleedings and spermatogenesis; colored transparencies showing stages in the production of ovulation in the three forms mentioned; photomicrograph of the artificially produced follicles by the hormone of pregnant mare's serum in various stages; photomicrographs and drawings illustrating the development of the follicle and its migration to the surface; graphs showing the biologic assay and methods of extraction of the hormone of pregnant mare's serum; a graph of actual ovulation during the cycle; photomicrographs of endometrial studies of anovulatory bleedings and the effect of the hormone of pregnant mare's serum; charts showing the clinical application of the hormone of pregnant mare's serum.

DOUGLAS P. MURPHY, Philadelphia:

Characteristics of the Uterine Contractions of Late Pregnancy: Exhibit of a tocograph with tracings taken at intervals of several days throughout the last two months of pregnancy, as secured from five patients; graphs to indicate the progressive increases in the various characteristics of the recorded waves; tracings taken from a collection of records made on 100 other patients to illustrate peculiar characteristics of uterine motility.

MOTION PICTURES

F. B. ZENER, NORMAN A. DAVID and H. F. VEHRS, University of Oregon Medical School, Portland:

Vioform N. N. R. in the Combined Treatment of Vaginal and Intestinal Trichomonas.

WILLIAM H. VOGT, St. Louis University School of Medicine, St. Louis:

Obstetric Practice.

Section on Ophthalmology

The section exhibit committee of the Section on Ophthalmology consists of Georgiana Dvorak-Theobald, Oak Park, Ill., chairman; Theodore E. Sanders, St. Louis, and Derrick T. Vail Jr., Cincinnati.

JOHN J. PRENDERGAST, St. Paul:

Ocular Leprosy: Exhibit of photographs of gross and microscopic lesions and sections, and microscopic sections.

L. T. POST, Washington University School of Medicine, St. Louis:

Studies on Inclusion Blenorrhea: Exhibit demonstrating the incidence, pathologic changes and diagnosis of inclusion blenorrhea; specimens showing the anatomy of the levator muscle in relation to ptosis and the use of fluorescence in lens surgery.

LEO L. MAYER, Chicago:

Optic Pathways in the Brain: Exhibit of an enlarged pictured section of one half of the cerebrum, the cuts united by strings showing the optic pathways and legend of the surrounding important structures; drawings of the brain from lateral, ventral, dorsal views showing the pathways (schematic).

THEODORE J. DIMITRY, New Orleans:

Evolution of a Sucking Disk for Extraction of Cataractous Lens in Capsule: Exhibit of drawings of and the different instruments used in the past and at the present time to remove the lens by a vacuum gripping; original instruments and one not larger than a fountain pen, showing that the disk placed in contact with the lens is quite flat.

JAMES H. ALLEN, University Hospital, Iowa City:

Staphylococcic Conjunctivitis: Exhibit showing clinical stages of staphylococcic conjunctivitis both by colored drawings and by models of the external eye; colored drawings illustrating the experimental reproduction of the disease by means of toxin and by means of staphylococcus inoculations in rabbits and in human volunteers; rabbits in which the disease has been reproduced by both methods demonstrated.

FREDERICK A. DAVIS, University of Wisconsin Medical School, Madison:

Primary Tumors of the Optic Nerve, a Phenomenon of Von Recklinghausen's Disease: Exhibit of photographs and photomicrographs with descriptions, showing primary tumors of the optic nerve associated with this syndrome.

LOUIS BOTHMAN and R. W. BENNETT, University of Chicago, Chicago:

Photography of the Eye: Exhibit of stereoscopic photographs of unusual and rare diseases of the fundus and stereophotographs of diseases of the anterior segment.

W. H. LUEDDE, C. T. EBER, L. C. DREWS, J. T. ELZ and F. W. LUEDDE, St. Louis:

Ophthalmic Physiology and Pathology: Exhibit of photomicrographs and charts illustrating the mechanism of accommodation; photomicrographs in color illustrating interesting conditions in ophthalmic pathologic conditions, with special review of interesting specimens in Wintersteiner collection; demonstration and measurement of simultaneous color contrast; clinical studies of retinal tears and retinitis pigmentosa.

Section on Laryngology, Otology and Rhinology

The representative to the Scientific Exhibit from the Section on Laryngology, Otology and Rhinology is Lee Wallace Dean Jr., St. Louis.

HARRY N. GLICK, St. Louis:

Anatomy and Surgery of Temporal Bone: Exhibit of charts and photographs and dry and wet specimens to show anatomy of fetal, infant and adult temporal bone; dry and wet anatomic material showing various operative procedures on the temporal bone.

THEODORE E. WALSH and PAUL R. CANNON, University of Chicago, Chicago:

Some Effects of Commonly Used Nasal Medications on the Lungs: Exhibit of transparencies of photomicrographs of lungs of animals treated intranasally with various commonly used nasal medications, together with some photomicrographs of human material; specimens of lungs of animals similarly treated, cleared by the Spalteholtz method; medications considered under the headings of oils, antiseptics and astringents; the increasing incidence of lipoid pneumonia in human beings, in adults as well as in children, showing the ease with which nasal medicaments may reach the lungs and the importance of knowing what effects such medicaments may have on normal lungs.

C. C. BUNCH, Washington University School of Medicine, St. Louis:

Deafness from Acoustic Trauma: Exhibit presenting an audiometric study of patients who have been deafened or made hard of hearing because of excessive stimulation by loud noises; cases of deafness in metal workers, hunters and soldiers, telephone operators, tractor drivers and the like, comparisons being made between deafness of this type and that from other common types of nerve involvement or other involvement of the inner ear.

MILLARD F. ARBUCKLE and A. C. STUTSMAN, St. Louis:

Bronchoscopy as an Aid in the Diagnosis and Treatment of Disorders of the Chest: Exhibit demonstrating the diagnosis of nonopaque foreign body in tracheobronchial tree; endobronchial neoplasms; diagnosis and treatment of lung abscess; lung mapping for localization and extent of bronchiectasis and other disorders.

MAX CUTLER, Chicago Tumor Institute, Chicago:

Cancer of the Larynx: Exhibit of charts, models and photographs, gross specimens, photomicrographs and roentgenograms of the soft tissue demonstrating (*a*) anatomy of the larynx, (*b*) clinical types and anatomic locations of laryngeal carcinomas, (*c*) clinical examination and methods of diagnosis of laryngeal carcinomas, (*d*) histopathology, (*e*) treatment and (*f*) results.

EDWARD C. ARMBRECHT, Wheeling, W. Va.:

Oral Surgery: Exhibit of photographs taken before and after operation of oral surgical conditions found in patients, such as

fractures of the jaw, oral tumors, cleft lip and cleft palate and miscellaneous conditions comprising impacted teeth, unusual deformities of the teeth, oral manifestations of certain systemic diseases, foreign bodies found in the mouth and so on; charts analyzing series of cases on fractures of the jaw, blood observations and anesthesia in oral cases.

JAMES B. COSTEN, St. Louis:

The Mandibular Joint Syndrome; A Symptom Complex of Pain and Ear Symptoms Produced by Disturbed Function of the Temporomandibular Joint: Exhibit of photostat enlargements of descriptive legends detailing the symptoms; anatomic drawings illustrating the structural basis of the disease; enlarged copies of roentgenograms of typical mandibular joint destruction; selected number of roentgenograms showing no destruction but showing uneven position of the condyles within the fossa; examples of trismus.

J. R. LINDSAY, University of Chicago, Chicago:

Suppuration in the Petrous Pyramid; Pneumatization of the Pyramid; Histopathology of Suppuration; X-Ray Demonstration: Exhibit showing that the development of pneumatized areas around the labyrinth and in the apex of the temporal bone follows certain definite patterns, and that exact knowledge of these patterns of pneumatization is essential for accurate diagnosis in acute and chronic suppuration and for a systematic and efficient method of surgical approach; each type or pattern of pneumatization demonstrated by selected temporal bone sections, photographs of gross specimens and diagrams for orientation; roentgenograms illustrating both normal pneumatization and the appearance when suppuration is present in each of these areas, both acute and chronic; serial sections from fatal cases of petrositis which illustrate the pathologic changes of suppuration in each of the pneumatized areas demonstrated anatomically.

DOROTHY WOLFF, VICTOR GOODHILL, ROBERT OWSLEY, J. W. WOODROW, S. LAURENCE KEMPLER and LEONARD G. ROSENTHAL, Washington University, St. Louis:

Anatomy and Pathology of Middle and Inner Ear: Exhibit of colored lantern slides showing anatomy and pathologic changes of temporal bone; microprojection of microscopic slides of temporal bone; phylogenetic explanation of juxtaposition of cochlea and organ of equilibrium; graduate student preparation of dissections of membranous labyrinth in fish and human beings; human fetal and term bony labyrinth dissections; human woods metal casts; bony labyrinth dissections of birds.

T. E. CARMODY, Denver:

Pathologic Conditions of the Mouth and Face: Exhibit of pathologic conditions of the mouth and face and the operative procedure for treatment; cleft lips and palate, carcinoma, tumors of lips, tongue and gums, osteomyelitis of the jaw, plastic surgery of the nose and face and the like, illustrated with still and motion pictures, many in color.

LOUIS J. BIRSNER, Washington University School of Medicine, St. Louis:

Anatomic Exhibit: Exhibit of specimens.

MOTION PICTURE

T. E. CARMODY, Denver:

Pathologic Conditions of the Mouth and Face.

Section on Pediatrics

The representative to the Scientific Exhibit from the Section on Pediatrics is Arthur F. Abt, Chicago.

ISAAC SCHOUR and H. G. PONCHER, University of Illinois College of Medicine, Chicago:

Calcium Metabolism and Teeth: Exhibit of charts, transparencies and reconstruction models which demonstrate on the basis of experimental and clinical data that growing and adult teeth differ in their response to calcium metabolism: (1) during their period of growth and calcification the enamel and dentin reflect accurately changes in calcium metabolism but are not subject to calcium withdrawal and, when fully developed, present a permanent record which cannot be altered by calcium therapy; (2) the calcification pattern of the enamel and dentin constitutes a kymographic reflection of the developmental pattern of the growing individual (prenatal, infancy and childhood periods, demarcated by the neonatal, infancy and childhood rings); (3) the periodontal tissues grow continuously and therefore give a transitory record of the present in the adult as well as the young individual.

THEODORE O. ELTERICH, Pittsburgh:

Problems in Childhood Endocrinology, Mental Deficiency and Associated Constitutional Anomalies: Exhibit of illustrated case histories of interesting children encountered and followed over a period of years, demonstrating respectively disturbances of the pituitary, thyroid and adrenal glands and the pancreas and gonads; observations on cases of pseudohermaphroditism, hermaphroditism, hypertelorism and several unusual types of constitutional anomalies; data indicating at least partial relationship of endocrine factors to such clinical conditions as pseudohypertrophic muscular dystrophy, asthma and chondrodystrophy.

ALEXIS F. HARTMANN, HENRY L. BARNETT, ANNE M. PERLEY and MARY B. RUHOFF, St. Louis:

The Use of Sulfapyridine in Infants and Children: Exhibit describing the drug and its chemical constitution, absorption-excretion data, toxicity and effect on bacterial infections; clinical charts on cases of pneumonia, peritonitis, meningitis and other infections, including Streptococcus viridans endocarditis; toxicity and changes in acid-base balance (similar to sulfanilamide), methemoglobinemia and cyanosis and control with methylene blue (similar to sulfanilamide).

MAURICE L. BLATT and ELLIS H. HARRIS, Chicago:

A Diet for the Premature Infant: Exhibit showing collection of breast milk, preparation of formulas in the diet kitchen, equipment and methods of feeding premature infants, the stool of the premature infant, growth of premature infants on specific diets; mortality rates arranged according to birth weight.

PRISCILLA WHITE and RICHARD WAGNER, Boston:

Diabetes in Youth: Exhibit showing the etiology, incidence, distinctive features of onset, constitutional factors, complications, treatment, hypoglycemia and prognosis of diabetes in youth; infants of diabetic mothers.

WILLIAM W. ANDERSON, Atlanta, Ga.:

Congenital Lung Cysts: Exhibit dealing with the occurrence, the incidence in the very young, the rapid expansion in intercurrent infection, as pneumonia, the air-trap and air-expansile type and the theories as to the formation of congenital lung cysts.

H. D. PALMER, Rockford Hospital, Rockford, Ill.:

Congenital Heart Disease: Exhibit showing the various forms of congenital heart disease illustrated by oil painted models cast from actual specimens; photographs, photomicrographs, roentgen films (on lantern slides shown in small illuminated boxes), drawings and specimens arranged to show the details of the various manifestations exhibited.

Section on Pharmacology and Therapeutics

The representative to the Scientific Exhibit from the Section on Pharmacology and Therapeutics is Wallace M. Yater, Washington, D. C. In addition to other exhibits, the section is contributing to the Exhibit Symposium on Heart Disease and to the group of exhibits on pneumonia.

SINCLAIR LUTON, St. Louis:

Major Error Involved When Droppers, Including the U. S. P. XI, Are Used in Measuring Fluid Digitalis Preparations: Exhibit illustrations, photographs and the like of historical material; graphs (1809-1900) showing differences in drop commonly printed in standard textbooks; graph showing opinion of forty clinicians as to the size of digitalis drop, with dosage error; table showing results obtained when fourteen commonly used droppers are used with ten "tinctures" of digitalis and with water and apertures measured; graph based on this table demonstrating the exact figures with a given combination, together with the dosage error; dosage error circle graph; statement as to dosage error to be avoided by dry digitalis; proper measuring (no droppers); charts showing results of U. S. P. XI dropper with water and tincture of digitalis; bottles with tincture in suitable vehicles.

FREDERICK STEIGMANN, Chicago:

Therapy of Icterus: Exhibit of drawings and microscopic slides showing the sites of origin of the different types of jaundice, their pathogenesis, etiology and variations in bile pigment

metabolism; posters showing etiologic and diagnostic factors in jaundice; a detailed therapy of icterus shown by means of posters; the "rest-and-work therapy" methods for liver disease complicated by jaundice, with the emphasis placed on the causal treatment.

THOMAS FITZ-HUGH JR., Philadelphia, and ADOLPH J. CREVOFF and HARRISON F. FLIPPIN, Hospital of University of Pennsylvania:

Idiosyncratic Effects of Certain Drugs on the Blood and Blood-Forming Tissues: Exhibit of charts, photomicrographs, slides and transparencies presenting the newer knowledge of allergic-like reactions of the blood and of blood-forming tissues to certain drugs; the clinical syndromes of hematologic importance which result from such causes, together with lists of drugs and proprietaries that have been suspected or proved as causes; certain possible conditioning mechanisms illustrated in support of the theory of "conditioned toxicity"; a file of reprints, case histories and journal articles.

GEORGE W. THORN, R. PALMER HOWARD, KENDALL EMERSON JR., and WARFIELD M. FIROR, Johns Hopkins University and Hospital, Baltimore:

Studies on Desoxycorticosterone (A Synthetic Adrenal Cortical Substance): Exhibit of charts, photographs and roentgenograms of patients who have been treated successfully both by injections of the synthetic hormone in oil and by subcutaneous implants of pellets of crystalline material; demonstration of the apparatus used for making pellets and a demonstration of the pellets used in implantation.

HUGH R. BUTT and JESSE L. BOLLMAN, Mayo Clinic, Rochester, Minn.:

Vitamin K in the Control of Hemorrhage in Jaundice: Exhibit of charts and figures showing the sources of vitamin K, its effect on the experimental animal and its effect on the human, with the hemorrhagic diathesis of jaundice; comparison of the quantitative and qualitative methods of measuring the prothrombin level in the blood of these patients and the effect of vitamin K on the level of prothrombin will be illustrated; effects of the vitamin and bile in the prevention and control of the hemorrhagic diathesis in jaundice is illustrated by charts and typical case histories.

SAMUEL H. SEDWITZ, Youngstown, Ohio, and C. E. SANDERS, Kansas City, Kan.:

Various Modes of Treatment of Peripheral Vascular Diseases: Exhibit showing treatment of patient on vasoscillator bed with intermittent venous compression; "homemade" suction pressure apparatus; intermittent venous compression (Collens-Wilensky), mecholyl by iontophoresis, whirlpool bath and paraffin bath; charts of classification of diseases and treatment; photographs of patients before and after treatment; demonstration of a stool for patient's use while resting.

ARTHUR F. ABT and CHESTER J. FARMER, Northwestern University Medical School, Chicago:

Vitamin C; Pharmacology and Therapeutics: Exhibit dealing with the pharmacology of vitamin C; sources of vitamin C; normal requirements of vitamin C; methods of determining the vitamin C in blood, urine and feces; pitfalls of various methods proposed; influence of dietary intake on the blood level and the excretion in urine and feces; requirements for pregnant and lactating women and for the breast-fed and artificially fed infant; renal excretion of vitamin C; effects of artificial fever on vitamin C blood levels; intravenous administration and excretion in urine and feces; subjects dealing with the therapeutics of vitamin C; avitaminosis due to malabsorption, achlorhydria and destruction in the intestinal tract; vitamin C requirements in infectious diseases as in scarlet fever, diphtheria and rheumatic fever; therapeutic need in gastric ulcer; sensitivity to arsphenamine and in wound healing; relationship to conditions of the teeth and cataract; demonstration of scurvy.

Section on Pathology and Physiology

In addition to a large group of exhibits on pathology and physiology, the section is contributing to the Exhibit Symposium on Heart Disease. The representative to the Scientific Exhibit from the section is Frank W. Konzelmann, Philadelphia.

F. P. MCNAMARA, Finley Hospital, Dubuque, Iowa:

Significance of Necropsy Studies in a 100 Bed Hospital: Exhibit based on an analysis of 550 necropsies in a 100 bed hospital consisting of tables and charts which show the principal lesions encountered, the primary and contributory causes of death, the gradual increase in the number and percentage of necropsies and the improvement in antemortem diagnosis; copies of the necropsy records and of reprints based on clinical and necropsy studies showing the value of necropsies in stimulating the utilization of material available in every hospital for continuous postgraduate education.

C. ALEXANDER HELLWIG, St. Francis Hospital, Wichita, Kan.:

The Diffuse Colloid Goiter (Structure, Function and Experimental Production): Exhibit of transparencies, photographs and photomicrographs illustrating structure and function of the colloid goiter; specimens of surgical goiter illustrating that diffuse colloid goiter is the most important type of goiter in North America; experimental colloid goiter in white rats, produced by calcium-rich diet and relatively high iodine content.

B. S. KLINE, A. M. YOUNG and R. STRAUS, Mount Sinai Hospital, Cleveland:

Healing with Pseudodiverticulum Formation Following Perforation in Acute Appendicitis: Exhibit of specimens, photographs and photomicrographs showing acute inflammation of the walls, perforation, progressive healing and pseudodiverticulum formation.

EDWARD R. JANJIGIAN, Danville State Hospital, Danville, Pa.:

The Basmeter, A New Method of Estimating the Basal Metabolic Rate: Exhibit of drawing of the basmeter with a small model of the basmeter and a sliding rule; charts and tables, showing the factors influencing the basal metabolic rate, their distribution and the like; tables evaluating the reliability of the basal tests; tables showing fundamental metabolic steps in metabolism of carbohydrates, proteins and fats, and their bearing on basal metabolism; technic of determining the basal rate on the basmeter and comparison of results with those of the basal machines; summary of certain points to bear in mind in diagnosis and surgery of the thyroid.

KERMIT CHRISTENSEN, St. Louis University School of Medicine, St. Louis:

Innervation Studies; Autonomic Innervation of the Orbit and of the Teeth: Exhibit of charts and photomicrographs showing the innervation of the orbit and the teeth.

ALRICK B. HERTZMAN, St. Louis University School of Medicine, St. Louis:

Photo-Electric Plethysmography; Clinical Applications to the Peripheral Circulation: Exhibit of photo-electric plethysmographs for the digits (fingers and toes), the nasal septum and the skin; plethysmograms from normal and abnormal conditions; use of the skin plethysmograph for estimating the cutaneous blood supply.

CHARLES GESCHICKTER, Johns Hopkins Hospital, Baltimore:

Forms of Mammary Cancer and Their Experimental Production in the Rat: Exhibit of photographs, charts, gross specimens and whole mounts of mammary glands illustrating clinical and experimental pathologic changes of mammary cancer; adenocarcinoma, duct carcinoma and scirrhous cancer (infiltrating form) with metastases to the lung has been produced in the male and female rats of the standard Wistar strain normally free from breast tumors; the exhibit shows the pathologic condition of the experimental tumor and the method of production and the corresponding human forms of mammary cancer and their known etiologic factors.

WILLIAM C. LANGSTON, WILLIAM J. DARBY and PAUL L. DAY, University of Arkansas, Little Rock:

Nutritional Cytopenia (Vitamin M Deficiency) in the Monkey: Exhibit of charts and photographs illustrating the anemia and leukopenia in monkeys resulting from vitamin M deficiency; evidence presented that this cytopenia is not the result of a deficiency of vitamin A, vitamin D, thiamin, riboflavin, ascorbic acid, nicotinic acid or inorganic elements; certain liver extracts and yeast were effective in preventing and curing the cytopenia; yellow bone marrow preparation and nucleic acid were ineffective; stained blood specimens for microscopic examination.

J. WILLIAM WHITE, Scranton, Pa.:

Carcinoma of the Uterine Cervix: Exhibit of placards showing etiology, incidence, pathologic changes, symptoms, signs, classification, regional metastatic spread, statistics, diagnosis and treatment; photomicrographs and microscopic slides showing various types of cervical cancer; drawings of early cancer of the cervix; models of stages of the disease and models, records and diagrams of radium applications.

HERBERT T. KELLY, EDMUND L. HOUSEL and WILLIAM M. EMREY, Philadelphia:

Deficiency Disease: Exhibit of charts and illustrations indicating the importance of the minor quantities of the diet, which are of major importance in the maintenance of the state of good health; a simplified syndrome of these conditions together with their effect; chart indicating the quantitative composition (vitamins, calories and minerals) of the various items of the American diet by which a quantitative assay of an average twenty-four hour intake for the individual patient may quickly and easily be determined; emphasis placed on the factors of supply, demand, absorption and utilization so that a rational therapy may be determined.

JOSEPH ERLANGER and A. S. GILSON JR., Washington University Medical School, St. Louis:

The Mechanism of the Production of the Sounds Emitted by an Artery During Pressure Determinations: Exhibit of records showing the movements of the freed wall of an artery in situ at the point at which and while it is being decompressed as in making blood pressure determinations, and also of apparatus with which such records can be obtained; development of the relevant phenomena (the preanacrotic or breaker phenomenon and the sounds) in a simple model.

TEMPLE FAY and LAWRENCE W. SMITH, Temple University School of Medicine, Philadelphia:

Temperature Factors in Cancer and Embryonal Cell Growth: Exhibit demonstrating a bedside unit used in the refrigeration therapy of cancer along with the various instruments devised for treatment of different parts of the body; a series of cleared chick embryos incubated at progressively reduced temperatures showing the fundamental biologic character of the temperature factor in cell growth; transparencies of chick embryos and progressive biopsy specimens from cancer patients under treatment.

ALBERT KUNTZ, P. A. CONRATH and W. F. ALEXANDER, St. Louis University School of Medicine, St. Louis:

The Autonomic Nervous System: Exhibit of charts illustrating the anatomic relationships of the sympathetic and parasympathetic divisions of the autonomic nervous system and the innervation of visceral organs, accompanied with anatomic preparations.

BENJAMIN T. TERRY, Tacoma General Hospital, Tacoma, Wash.:

Rapid Section Technic: Exhibit showing how to cut, stain and have ready for microscopic examination in sixty seconds sections of fresh unfixed tissue; how to cut, stain and have ready for immediate microscopic examination sections of fixed malignant tissues; the technic for sectioning and staining difficult tissues; directions and diagrams given away for making an inexpensive, efficient cutter, cutting board and stain.

Section on Nervous and Mental Diseases

The representative to the Scientific Exhibit from the Section on Nervous and Mental Diseases is Roland P. Mackay, Chicago. Motion pictures will be shown in an adjoining area in addition to the exhibits.

CHARLES P. LARSON, Western State Hospital, Fort Steilacoom, Wash.:

Occurrence of Brain Tumors in Mental Hospital Patients: Exhibit of watch-glass mountings of different types of brain tumors which were found during the course of routine autopsies performed on patients dying at the Western Washington State Mental Hospital; statistical survey of the number and types of brain tumors encountered in a three-year period showing that in 13.5 per cent of all the autopsies performed during this period some type of intracranial tumor was found; charts demonstrating the correlation between the mental status of the patient and the situation of the tumor.

G. WILSE ROBINSON and G. WILSE ROBINSON JR., Neurological Hospital, Kansas City, Mo.:

Delirium: Exhibit showing the causes, pathologic changes and treatment, pointing out that delirious manifestations always arise from the same pathologic condition and that when delirium does arise it indicates a serious physical condition, somewhat similar to shock, although its effects are localized, and that the pathologic condition behind the delirium must be treated as well as the primary condition which, through a series of cycles, has produced delirium.

WALTER L. BRUETSCH and MAX A. BAHR, Central State Hospital and Indiana University School of Medicine, Indianapolis:

Psychoses with Chronic Rheumatic Brain Disease: Exhibit of charts showing the frequency of rheumatic changes of the brain found at autopsy of institutionalized mental patients; photographs illustrating the nature of the gross and microscopic lesions in the brain and heart of these patients.

RALPH M. STUCK, Denver:

Surgical Epilepsy: Exhibit of artists' drawings and displays telling the important facts to be gathered in the history, showing normal anatomic physiology and most of the pathologic lesions in epilepsy amenable to surgery.

ABRAHAM MYERSON and LEO ALEXANDER, Boston State Hospital, Mattapan, Mass.:

Mineral Studies of the Brain by Means of Microincineration and Spectroscopy: Exhibit of apparatus used; photomicrographs of normal and pathologic brain tissue; reproductions of spectroscopic graphs.

J. F. FULTON and MARGARET A. KENNARD, Yale University, New Haven, and CARLYLE F. JACOBSEN, Washington University, St. Louis:

Functions of the Frontal Lobe with Particular Reference to the Motor and Premotor Areas (Areas 4 and 6 of Brodmann): Exhibit of a series of diagrams, brain models and motion picture showing functions of the frontal lobe with particular reference to the motor and premotor areas.

MOTION PICTURES

Motion pictures will be shown continuously throughout the week, among which will be the following:

J. RUDOLPH JAEGER, Denver:

Lumbar Sympathectomy for Traumatic Sciatic Neuritis.
Repair of Bone Defect in Skull.
Spinal Cord and Cauda Equina Injury.
Frontal Lobe Tumor.
Diagnosis of Brain Lesions by Injection of Air.
Herniated Intervertebral Disk (with Sciatic Neuralgia).
Tic Douloureux (Diagnosis and Treatment by Alcohol Injection and Operation).

HENRY R. VIETS and ROBERT SCHWAB, Boston:

Myasthenia Gravis; a Historical, Clinical and Therapeutic Survey.

J. F. FULTON and MARGARET A. KENNARD, Yale University, New Haven, and CARLYLE F. JACOBSEN, Washington University, St. Louis:

Functions of the Frontal Lobe with Particular Reference to the Motor and Premotor Areas (Areas 4 and 6 of Brodmann).

A. E. BENNETT, Omaha, Neb.:

Convulsive Shock Therapy in Affective Psychoses.

Section on Dermatology and Syphilology

The representative to the Scientific Exhibit from the Section on Dermatology and Syphilology is Hamilton Montgomery, Rochester, Minn. In addition to the exhibits, motion pictures will be shown in an adjoining area.

ELMORE B. TAUBER and H. G. REINEKE, University of Cincinnati College of Medicine, Cincinnati:

Atypical Forms of Bone Syphilis: Exhibit of charts, photographs and roentgenograms, showing an unusual series of bone syphilis; the typical bone syphilis of prenatal and acquired syphilis compared with selected cases of bone syphilis of very unusual types; cases will show that the complete examination and follow-up studies, in addition to the roentgenograms, will frequently make the diagnosis of unusual forms of bone syphilis.

ERWIN P. ZEISLER, Chicago:

Diseases of the Tongue, Lips and Oral Mucosa: Exhibit of photographs, colored drawings and photomicrographs illustrating the differential diagnosis of syphilitic and nonsyphilitic disease and of cancerous and precancerous lesions of the mouth; a pictorial review of oral disorders with particular reference to those seen in dermatologic practice.

JOSEPH B. HOMAN, Department of Medical Art, University of Cincinnati College of Medicine, Cincinnati:

Value and Limitations of Infra-Red Photographs in Dermatology: Exhibit of charts describing the exact technic of infra-red photography; various types of large photographs illustrate the practical value and limitations of such photography.

MORRIS MOORE, Barnard Free Skin and Cancer Hospital, St. Louis:

Mycotic Infections of Man: Exhibit of clinical photographs of the various mycoses, superficial and deep, in the epidermis, dermis and internal viscera; photomicrographs showing the organism in situ and the histopathologic changes; illustrations and drawings of various fungi; cultures of the fungi in Petri dishes; experimental work on mycoses showing inoculation of the chorio-allantoic membrane of the chick with pathogenic fungi, photomicrographs and the like; experimental work on pityriasis versicolor and seborrheic dermatitis.

GEORGE SCHWARTZ, Boston:

Color Photography in Skin Diseases: Exhibit of lantern slides taken in color with Kodachrome film, showing various cutaneous diseases and syphilis; exact reproduction of the natural color that is characteristic of the particular cutaneous disease shown and the almost lifelike reproduction of the minute details of the lesions, such as macule, papule, vesicle or bulla; pictures of all the common cutaneous diseases and many of the rare ones; some slides show the entire distribution of the lesions on the face and body, while others are close-ups of the individual lesion.

BEDFORD SHELMIRE and H. L. GRAHAM, Dallas, Texas:

Survey of Common Weeds Causing Contact Eczema; Patch-Testing with Their Oils: Exhibit of mounted specimens and photographs in natural habitat of some sixty common weeds considered in survey; charts showing sensitization index of various weeds and occupations of persons affected; demonstration of plant oils, their method of extraction and mode of application to the skin for patch-testing; maps showing national distribution of weeds employed in survey; charts exhibiting reactions in noneczematous controls.

J. K. HOWLES and WILLIAM BRANKS STEWART, Louisiana State University, New Orleans:

Cutaneous Manifestations of Syphilis: Exhibit of paintings from life and plaster molds painted from life on the various cutaneous manifestations of syphilis, including primary, secondary and tertiary lesions.

MOTION PICTURES

Motion pictures will be shown on a regular schedule, among which will be the following:

JOHN G. DOWNING, Boston:

A Clinical and Laboratory Study of Fungous Diseases Demonstrated by a Colored Motion Picture.

MYLES STANDISH, Hartford, Conn.:

Psoriasis.

SAMUEL AYRES, Los Angeles:

Acne Rosacea.

FRED WISE, New York:

Common Lesions of the Eyelids.

C. FERD LEHMANN, San Antonio, Texas:

Leprosy.

LOUIS A. BRUNSTING and HAMILTON MONTGOMERY, Rochester, Minn.:

Skin Lesions of the Legs.

Section on Preventive and Industrial Medicine and Public Health

The representative to the Scientific Exhibit from the Section on Preventive and Industrial Medicine and Public Health is Paul A. Davis, Akron, Ohio.

CARL F. JORDAN, Iowa State Department of Health, Des Moines:

Rocky Mountain Spotted Fever: Exhibit of mounted specimens of some of the animal hosts (chipmunk, ground squirrel, rabbit and dog) and a diagram indicating the various stages in the life history of the common dog tick Dermacentor variabilis; live and preserved specimens of the different stages of the wood tick, natural size and magnified; information relative to the clinical and epidemiologic aspects of Rocky Mountain spotted fever and the reported occurrence of the disease in the northern and southern central states area.

ROBERT A. BLACK, O. C. WENGER, LAWRENCE J. LINCK and MARVIN B. OSTERMAN, Chicago Board of Health, Chicago:

Chicago Syphilis Control Program: Exhibit depicting the activities of the Chicago Syphilis Control Program, which is a cooperative enterprise, conducted by the Chicago Board of Health, with the assistance of the Illinois Department of Public Health, United States Public Health Service and the Works Progress Administration; activities include statistical research, public education, free laboratory service, information, consultation service, follow-up and drug distribution service, mechanical system for automatic reporting on treatment-progress and control of venereal disease; a city-wide case finding program.

PHILIP L. VARNEY, Washington University School of Medicine, St. Louis:

Modern Therapy and Prophylaxis of Tetanus: Exhibit showing that the most advanced present day methods of therapy and prophylaxis of tetanus have greatly increased the chances for survival of tetanus patients and, if properly applied, should eliminate the possibility of the development of idiopathic tetanus; mortality rates in properly and improperly treated patients compared; a step-by-step outline of the proper methods, illustrated by means of apparatus, photographs, charts and graphs, including the procedures and equipment used in the preparation of plain and alum-precipitated toxoid and methods for its administration.

CHARLES WALTER CLARKE, New York:

Quackery and Other Unqualified Practices in Relation to Syphilis and Gonorrhea: Exhibit of collection of patent nostrums on the present market with analyses of their contents; charts and maps showing extent and distribution of unqualified practices; common quack advertising; photographs and literature; information about quack practitioners; also about kind and extent of drugstore counter prescribing.

BERT R. BOONE, United States Public Health Service, Washington, D. C.:

Stethography in School Children: Exhibit of photomurals portraying the methods and the technic in obtaining heart sound tracings from elementary school children; tracings and charts describing several important characteristics and variations of heart sounds found in school children; illuminated glass panels showing, by means of appropriate mechanisms, the continuous production of typical heart sound tracings in an enlarged form.

D. L. HARRIS, Washington University School of Medicine, St. Louis:

Rabies; Epidemiology and Prophylaxis: Exhibit of charts, tables and photomicrographs showing pathologic changes and diagnosis of the disease and pathologic aspect of "treatment paralysis."

J. J. BRONFENBRENNER, DONALD M. HETLER, JACK MEHL BURNETT and FRANCES LOVE, Washington University School of Medicine, St. Louis:

Experimental Alimentary Allergy and Its Prevention: Exhibit of charts and photographs illustrating the fact that, by keeping guinea pigs on a scorbutogenic diet, it is possible to increase the rate of absorption through the digestive tract to such a point that all the animals are sensitized by feeding of soluble protein; allergic state can be elicited not only by the systemic introduction of antigen but also by the production of an anaphylactic syndrome as a result of test feeding; if sufficient vitamin is supplied to such hypersensitive, scorbutic animals, they no longer respond to oral administration of the antigen, while their sensitivity to systemic introduction of antigen remains unimpaired.

R. V. ELLIS and C. O. ROSENDAHL, University of Minnesota, Minneapolis:

Hay Fever Causes for Minnesota: Exhibit of charts presenting mounted herbarium specimens of the principal plants which produce hay fever-causing pollens in Minnesota; maps showing regional distribution and density of population for the plants mentioned; photomicrographs of pollen from each of the plants; graphs showing season and quantitative pollution of the air for each kind of pollen over a period of several years; charts evaluating the relative importance of the several causes in terms of clinical data.

Section on Urology

The representative to the Scientific Exhibit from the Section on Urology is R. S. Ferguson, New York.

HERBERT E. LANDES and HAROLD C. VORIS, Loyola University Clinics, Chicago:

Clinical Cystometry, an Aid to the Diagnosis of Neurologic and Urologic Lesions: Exhibit of (1) photograph of cystometer used in original studies; (2) portable cystometer used in later studies; (3) cystometrograms characteristic of various neurologic and urologic lesions; (4) chart showing nerve pathways involved in bladder function.

V. S. COUNSELLER and J. T. PRIESTLEY, Mayo Foundation, Rochester, Minn.:

Surgery of the Genito-Urinary Tract: Exhibit showing methods of subtotal vesical resection, of uretero-enterostomy and total cystectomy for cancer of the bladder outlined by photographs, charts and models; recent technical improvements in removing large stag-horn renal calculi are illustrated among the material collected pertaining to surgery of the kidney; plastic surgery for hypospadias and other genital abnormalities is shown.

W. F. BRAASCH and J. L. CRENSHAW, Mayo Foundation, Rochester, Minn.:

Recent Advances in Urologic Diagnostic Methods: Exhibit of roentgenograms, photographs and descriptive material stressing the importance of diagnosis in cases of hematuria; interesting cases of calculous disease, of infections in the urinary tract and the methods of diagnosing and treating them are outlined; the importance of microscopy and of ordinary laboratory methods in the handling of urologic cases emphasized in a manner interesting to both the general practitioner and the specialist.

H. L. WHITE, PETER HEINBECKER and T. FINDLEY JR., Washington University School of Medicine, St. Louis:

Some Hypophysial Influences on Renal Function: Exhibit of charts, diagrams, photographs and microscopic slides showing (1) the lesion responsible for the production of experimental diabetes insipidus; (2) the nonessentiality of the anterior lobe for polyuria; (3) acute responses to ingestion of water by hypophysectomized dogs and dogs with diabetes insipidus; (4) creatinine and urea clearances and maximum concentrating power of the urine in hypophysectomized dogs and dogs with diabetes insipidus; (5) urinary responses of normal and hypophysectomized dogs and rats to administration of anterior lobe and thyroid; (6) responses of clinical diabetes insipidus to ingestion of water and salt.

GEORGE H. EWELL, Jackson Clinic, Madison, Wis.:

Urography; Diseases and Injuries of the Genito-Urinary Tract: Exhibit of pyelograms, cystograms and urethrograms showing the value of roentgen examinations combined with urologic examination in the diagnosis and treatment of diseases and injuries of the genito-urinary tract; photographs and transparent drawings demonstrating some types of abnormalities in the genito-urinary tract; demonstration of the more common urologic conditions and many unusual cases.

GRAYSON CARROLL, BRANSFORD LEWIS and LOUIS KAPPEL, St. Louis:

Study of the Effect of Drugs on the Ureter: Exhibit of anatomic charts of the nerve supply of the urinary tract; tracings from intact human ureter showing effect of drugs; demonstration of simple method used to obtain these tracings; intravenous urograms demonstrating the effect of various drugs on the ureter; explanatory pamphlet.

G. J. THOMPSON, E. N. COOK, J. L. EMMETT, Mayo Foundation, Rochester, Minn.:

Transurethral Surgery: Exhibit of anatomic models, photographs, charts and descriptive matter pertaining to diseases of the ureter, bladder, prostate, seminal vesicles and urethra; the selection of cases, preoperative methods of treatment, transurethral operative technic and postoperative nursing care; working models illustrating practical points.

ROGER W. BARNES, Los Angeles:

Surgical Treatment of Vesical Diverticula: Exhibit of models showing the different steps in the technic of a new method for the surgical treatment of large vesical diverticula; also the technic for surgical treatment of small vesical diverticula, done through the cystoscope; drawings illustrating the technic, and cystograms, both preoperative and postoperative.

Section on Orthopedic Surgery

In addition to the exhibits of this section, there will be motion pictures on orthopedic surgery in an adjoining area. The representative to the Scientific Exhibit from the Section on Orthopedic Surgery is Frederick A. Jostes, St. Louis.

VERNON P. THOMPSON and JOHN S. STEPHENS, Los Angeles:

Compression Reconstruction of Recent Intracapsular Femoral Neck Fracture: Exhibit of drawings, models, skiagrams and specimens showing the influence of shear, compression, rotation and obliquity on the fragments; the effect of the reconstruction; the usual oblique femoral neck fracture allows muscle pull and weight bearing to exert a sharing action; removal of a small wedge from the top of the neck converts a relatively vertical fracture line into a relatively horizontal one; a compression relationship of the fragments is thereby established, secured by internal fixation.

MILDRED TROTTER, Washington University, St. Louis:

Accessory Sacro-Iliac Articulations: Exhibit of pelves which present the variations; tables showing the incidence according to race, sex and age in a series of 776 skeletons of the Washington University Department of Anatomy; prepared skeletons and wet preparations; microscopic sections.

JAMES GRAHAM, Springfield, Ill.:

Weak Foot; Pathogenesis and Treatment: Exhibit of models, sketches and roentgenograms portraying an anatomic and clinical study of the mechanical factors at play in the pathogenesis of the three common clinical varieties of weak foot (postural type, shortened achilles type and anatomic type); treatment of these varieties of weak foot; mechanical apparatus, with emphasis placed on the simplification of mechanical technic; relationships of abnormal body postures and weak feet to the field of general medicine and a more widely applicable approach to the therapy of these extremely common and troublesome conditions.

PAUL C. COLONNA and FREDERICK VOM SAAL, Crippled Children's Hospital, Oklahoma City:

Study of Amputations in the Lower Extremity: Exhibit of charts, photographs of patients and roentgenograms, models and various types of practical appliances; a critical analysis of about seventy-five unselected amputation stumps of the lower extremity, reviewing the cause, complications and end results; the use of temporary and permanent prosthesis with individual time intervals for weight bearing is described.

J. DEWEY BISGARD, Omaha:

Experimental Scoliosis: Exhibit of transparencies and gross specimens of spines of goats in which scoliosis was produced by arresting growth on one side of the vertebral bodies by destruction of the growth cartilage and also by laying grafts along one side of several contiguous bodies; growth of vertebral bodies was also measured by placing steel shot in the vertebra when the animals were approximately 2 weeks old and recording the growth by means of roentgenograms from that time until termination of major growth eight months later; the feasibility of fusing the spine by fusing vertebral bodies in certain cases is suggested.

PHILIP LEWIN, Chicago:

Backache and Sciatica: Exhibit of charts, transparencies and models demonstrating every phase of the subject from the standpoints of anatomy, etiology, pathologic changes, symptoms, differential diagnosis, treatment and end results.

WILLIS C. CAMPBELL and J. S. SPEED, Memphis, Tenn.:

Treatment of Ununited Fractures of the Neck of the Femur: Exhibit of illustrations of various procedures for ununited fractures of the neck of the femur, such as bone graft operation; reconstruction operations; osteotomies; roentgenograms of cases where these procedures have been used.

L. D. SMITH, Milwaukee:

Supracondylar Fracture of the Femur; Treatment by Acute Flexion: Exhibit of a model of a femur and tibia, showing a supracondylar fracture of the femur; traction of the leg increases the disalinement of the distal fragment; acute flexion of the knee releases the deforming muscle pull, tightens the quadriceps tendon anteriorly against the two bone fragments and alines them; the position maintains reduction and permits ambulation.

AUGUSTUS THORNDIKE JR. and ROBERT J. JOPLIN, Harvard Medical School, Boston:

Cellulose Compound Bandage; a Waterproof Splinting Material: Exhibit demonstrating the application of this bandage material; transparencies of actual cases on which this splinting material was used.

G. MOSSER TAYLOR, Los Angeles:

Manipulative Therapy: Exhibit of charts, art drawings and demonstrations with a living subject, outlining the indications, contraindications and complications, the critical positions for the maneuvers and the manipulations of all the joints in a regular well organized manner.

C. H. CREGO and H. R. MCCARROLL, St. Louis:

Early Treatment of Congenital Dislocation of the Hip, with Skeletal Traction: Exhibit showing results obtained in the treatment of early congenital dislocation of the hip with skeletal traction; a comparative study of the three types of congenital dislocation of the hip—posterior dislocation, upward subluxation and primary anterior dislocation; "before and after" photographs of individual patients of each group together with roentgenograms of a large series of cases bringing out the salient features of each type; materials used in an inexpensive form of skeletal traction with demonstrations on dolls.

MOTION PICTURES

Motion pictures on orthopedic surgery will be shown on a regular schedule throughout the week, among which will be the following:

FREDERICK A. JOSTES, St. Louis:

Backache, A Manipulative Method of Treatment Without Anesthesia.

H. THEODORE SIMON, New Orleans:

The More Common Fractures of the Upper and Lower Extremities; A Newer Method of Demonstrating Fundamental Principles of Treatment.

VERNON P. THOMPSON and JOHN S. STEPHENS, Los Angeles:

Compression Reconstruction of Recent Intracapsular Femoral Neck Fractures.

G. MOSSER TAYLOR, Los Angeles:

Manipulative Therapy.

EDWARD L. COMPERE, Chicago:

Rehabilitation of Poliomyelitis Victims.

LEO MAYER, New York:

Operative Treatment of Surgery of the Paralyzed Upper Extremity.

Section on Gastro-Enterology and Proctology

The representative to the Scientific Exhibit from the Section on Gastro-Enterology and Proctology is Sara M. Jordan, Boston.

DAVID ADLERSBERG and MICHAEL WEINGARTEN, Beth Israel Hospital, New York:

The Small Intestine in Nutritional Deficiency: Exhibit showing the effects of nutritional deficiency in the small intestine, consisting of (1) a characteristic symptom complex, (2) evidence of impaired fat digestion, (3) roentgen changes in the appearance of the small intestine; these changes are demonstrated in sprue and pellagra, in ulcerative colitis and in a group of cases of subclinical deficiency termed chronic nongranulomatous enteritis.

WILLIAM J. MARTIN JR. and JOSEPH C. BELL, Louisville, Ky.:

Sigmoidoscopic and Roentgenologic Diagnosis of Polypoid Lesions of the Large Bowel: Exhibit of roentgenograms of polypoid lesions of the large bowel, with both single and double contrast technic; charts outlining etiologic theories, sex incidence, age incidence, location incidence of malignant changes and the like, based on information obtained from sigmoidoscopic examinations; these are compared as to incidence, location and so forth, with the frank cases of carcinoma of the lower part of the bowel, demonstrated by sigmoidoscopic examination during the same period of time.

JOSEPH W. LARIMORE, St. Louis:

Diseases of the Intestine and the Colon: Exhibit of lantern slides, classified, arranged and illuminated, showing diseases of the intestine and colon.

W. WAYNE BABCOCK, DANIEL J. PRESTON and FRANCIS L. ZABOROWSKI, Temple University Medical School, Philadelphia:

Technical Improvements in Abdominal Surgery: Exhibit showing (*a*) technic in the formation of perineal colostomy, or the transfer of an objectionable abdominal colostomy to the perineum; (*b*) statistics and colored slides from more than 200 resections of the large bowel, illustrating technic and results; (*c*) internal exteriorization for increased safety of stage operations within the abdomen, especially those for the acute gallbladder or for appendical abscess; (*d*) the use of Sump drains for prolonged peritoneal drainage in the prevention and treatment of spreading peritonitis; (*e*) technic of enterostomy for ileus; (*f*) the rapid closure of small biliary fistulas; (*g*) the successful early closure of duodenal and other troublesome fistulas; (*h*) metallic sutures and ligatures for the more secure closure of clean and contaminated abdominal wounds; (*i*) muscle-splitting rectus retracting incision for resection of colon.

FRANK H. LAHEY, Lahey Clinic, Boston:

Diseases of the Gastrointestinal Tract: Exhibit covering the subjects of carcinoma of the esophagus, peptic ulcer, carcinoma of the stomach, diseases of the small intestine, ulcerative colitis, carcinoma of the rectum, and polyps of the colon and rectum.

HENRY A. RAFSKY, New York:

Diagnostic Criteria in the Differentiation Between Peptic Ulcer and Gastric Cancer: Exhibit of transparencies showing a series of cases in which the differentiation between peptic ulcer and gastric cancer presented diagnostic and therapeutic problems; routine procedures were not as a rule sufficient to make the distinction, and in most of the cases special methods of examination were necessary; investigations consisted of the secretory response, mucosal studies of the stomach, gastroscopy and various laboratory tests; evaluation of these diagnostic criteria will be discussed and their clinical application illustrated.

HARRY E. BACON and HESSER C. LINDIG, Temple University Medical School, Philadelphia:

Extrarectal Metastatic Growths from Malignant Conditions of the Upper Part of the Abdomen: Exhibits presenting a diversified series of cases in colored photomicrographs, roentgen examinations and moulage specimens to permit palpation and visualization of artificial growths; differential diagnosis shown by illustrations; frequently misinterpreted and misdiagnosed extrarectal metastatic growths from malignant growths of the upper part of the abdomen and the mamma.

WALTMAN WALTERS, Mayo Clinic, Rochester, Minn.:

Operative Technic in Treatment of Stricture of the Common Bile Duct: Exhibit showing different types of operative procedure; indications for the various methods and results of their application.

Section on Radiology

The representative to the Scientific Exhibit from the Section on Radiology is E. E. Downs,* Woodbury, N. J.

W. EDWARD CHAMBERLAIN and BARTON R. YOUNG, Temple University Hospital, Philadelphia:

A Harmless Method of Visualizing Ruptured Intervertebral Disks and Spinal Canal Tumors: Air Myelography. Exhibit of transparencies presenting roentgenograms, descriptive data and titles, and photographs illustrating technic.

* Deceased.

JOHN D CAMP, J. G LOVE and M N WALSH, Mayo Clinic, Rochester, Minn.

Intraspinal Protrusion of the Intervertebral Disks Exhibit illustrating the diagnosis of intraspinal protrusion of intervertebral disks as based on the patient's history and physical, orthopedic, neurologic and roentgenologic examinations, the value of lumbar puncture in the examination of the spinal fluid is indicated and the technic of the reversed Queckenstedt test described, the anatomy of the normal intervertebral disk and ligamentum flavum and the relation of these structures to the nerve roots illustrated by moulages, details of the roentgen examination of the spinal subarachnoid space by means of contrast agents shown by transparencies, roentgenograms and moving models, anatomic variations of the spinal subarachnoid space and the roentgenologic characteristics of protruded intervertebral disks and hypertrophy of the ligamentum flavum depicted by roentgenograms and transparencies, moulages illustrating the technic of the surgical removal of protruded intervertebral disks and the resection of the ligamentum flavum, the hypertrophy of which is an almost constant accompaniment of disk protrusion

EDITH H QUIMBY and JOHN POOL, Memorial Hospital, New York

Protection from Roentgen Rays and Radium Exhibit of charts, diagrams, photographs, tables, and other information regarding protection against different types of radiation, various aspects of protection, considered with respect to the patient, the physician, the technician, and the neighbors, types of injury resulting from undue exposure to radiation, data given according to which the necessary protection may be achieved

PAUL C SCHNOEBELEN, HERMAN M MEYER and I C MIDDLEMAN, St Louis

Roentgen Examination in Acute Intestinal Obstruction Exhibit showing the value and use of roentgen examination early in cases suspected of intestinal obstruction, serial films show a progressive accumulation of gas and fluid levels early in complete obstruction of small bowel, the signs of complete small intestinal obstruction discussed and demonstrated, case reports with conditions found at operation, literature reviewed and charts prepared for demonstration, complete obstruction in three cases demonstrated by roentgen examination four hours after onset of symptoms, cases proved by operation

LEROY SANTE, St Louis

Roentgenologic Aids in Abdominal Diagnosis Exhibit emphasizing some roentgenologic aids in diagnosis of certain surgical conditions of the abdomen and presenting evidence of the accuracy and value of certain less accepted roentgenologic signs and methods as seen in intestinal obstruction and paralytic ileus, ruptured hollow viscus from trauma and disease, significance of flank shadow in diagnosis of abdominal exudates and subdiaphragmatic abscess diagnosed by aid of pneumoperitoneum

HOWARD E SNYDER, Winfield, Kan

The Ambulatory Management of Fractures of the Lower Extremity Exhibit of photographs of patients and their roentgenograms before, during and after treatment by an ambulatory method, explanatory printed matter grouped with the photographic material for each patient, fractures of the foot, ankle, leg and thigh included, applied and unapplied models of a new type of walking iron are shown

JAMES F KEITY and D ARNOLD DOWELL, Creighton Medical School, Omaha

Prevention and Treatment of Gas Gangrene and Other Infections with a Mobile Roentgen-Ray Unit Exhibit consisting of clinical data on patients with gas gangrene treated with the mobile roentgen-ray unit, development of the roentgen ray as a means of prevention of gas gangrene, different clinical groups of gas gangrene infection and the roentgen treatment for each group outlined, status of the roentgen ray in this condition, increasing value of therapy with the roentgen ray unit in acute inflammations

L H GARLAND and HAROLD ARTHUR HILL, San Francisco

Diagnosis of Bony Union in Fractures of the Femoral Neck Exhibit of transparencies and original roentgenograms showing the classification and end results of treatment in fractures of the femoral neck and emphasizing that, since the classification is frequently valuable as a guide in selection of treatment and since the duration of certain types of internal fixation frequently depends on a roentgen diagnosis of bony union, exactitude in roentgen technic is important, complete details are presented concerning the type of technic used and the criteria on which a diagnosis of bony union may be made

EDMUND P HALLEY, Decatur and Macon County Hospital, Decatur, Ill., and PERRY J MELNICK, University of Illinois College of Medicine, Chicago

Carcinoma of the Breast, Value of Preoperative Irradiation and a Short Irradiation-Operation Interval Exhibit presenting histopathologic evidence for the value of preoperative irradiation in carcinoma of the breast and for a short time interval between irradiation and surgery, characteristic irradiation changes, previously found in experimental animal tumors, were found in this series of irradiated human breast cancers when amputation was done from three to four weeks after irradiation, from six to eight weeks after irradiation (the usual time interval) these changes were no longer present, but regrowth of the tumor and spread along the lymphatics frequently were found, photomicrographs and clinical data presented from this material

EXHIBIT SYMPOSIUM ON HEART DISEASE

The exhibit symposium on heart disease is presented in cooperation with the American Heart Association under the guidance of a committee, the chairman of which is Thomas M McMillan, Philadelphia

GEORGE P ROBB and ISRAEL STEINBERG, New York

Visualization of the Chambers of the Heart, the Pulmonary Circulation and the Great Blood Vessels in Man Exhibit shows the apparatus and technic of the method, contrast roentgenograms with appropriate controls showing the superior vena cava and tributary veins, the four chambers of the heart and their walls, the pulmonic and aortic valves, the pulmonary circulation and the thoracic aorta with the branches from the arch, illustration of the abnormalities found in the following types of heart disease (1) congenital, (2) rheumatic, (3) syphilitic, (4) hypertensive, (5) arteriosclerotic, (6) cor pulmonale, demonstration of abnormalities of the lung and mediastinum including stenosis, occlusion and displacement of the major division of the pulmonary artery occurring in mediastinal and hilar neoplasm and adenitis, enlargement of the pulmonary artery and decreased vascularity of the lung associated with pulmonary fibrosis

RALPH KINSELLA and R O MUETHER, St Louis

Experimental Reproduction and Cure of Streptococcic Endocarditis Exhibit showing steps and apparatus used in the reproduction such as instruments, drawings of operative field and photographs of injured valves, charts of cure with merthiolate and sulfanilamide, reproduction of endocarditis by feeding streptococci by mouth

JOHN H GIBBON, MARY H GIBBON and CHARLES KRAUL, Philadelphia

Studies on Massive Pulmonary Embolism with Demonstration on an Experimental Therapeutic Method Exhibit of charts and graphs illustrating physiologic effects produced by partial occlusion of the main pulmonary artery and the effects produced by occlusion of the branches of that artery, demonstration of apparatus used for the temporary maintenance of life in an animal with the pulmonary artery completely occluded

S C ROBINSON and MARSHALL BRUCER, Chicago

The Range of Normal Blood Pressure, Statistical and Clinical Study of 15 000 Persons Exhibit showing the distribution of systolic, diastolic, mean and pulse pressures in both sexes and in all age groups, the gross hypertensives are removed and the delimited sample is subjected to the same statistical treatment, conclusions concerning the range of normal blood pressure are drawn, added evidence for these conclusions is presented from a study of 500 persons with five to ten year continuous records, mortality data used as a check on the conclusions, from this evidence a new and more rational range of normal blood pressure is presented, a new view of hypertension is introduced, in addition the exhibit depicts the relation of obesity and body build to blood pressure

EDGAR A. HINES JR., Mayo Clinic, Rochester, Minn.:

The Significance of Vascular Hyperreactivity in Essential Hypertension: Exhibit of charts and demonstration with sound amplification of blood pressure readings showing (1) technic of the cold pressor test for measuring vascular reactivity; (2) the important role played by vascular hyperreactivity in the development of essential hypertension, particularly in regard to hereditary factors.

LOUIS N. KATZ and ANNE L. BOHNING, Michael Reese Hospital, Chicago:

Electrocardiogram in Coronary Disease: Exhibit of serial curves (including chest leads) to show electrocardiographic deviations occurring in coronary occlusion and in coronary sclerosis.

WILLIAM M. KINNEY, Joplin, Mo.:

Pulmonary-Vascular and Cardiac Changes in Silicosis: Exhibit of serial films of patients with silicosis to show cardiac enlargement which takes place as the disease progresses; photographs of hearts removed from silicotic patients at autopsy; photomicrographs of sections of myocardium and lung to show the myocardial changes and pulmonary vascular changes.

WILLIAM B. KOUNTZ, St. Louis:

Coronary Flow: Exhibit of charts showing the coronary flow in the human heart; each type of heart disease represented both from an anatomic and functional standpoint; photomicrographs and photographs of the coronary system as demonstrated by roentgen studies; physiologic and anatomic principles which cause variation in coronary flow shown by motion pictures.

WENDELL G. SCOTT and SHERWOOD MOORE, Washington University School of Medicine, St. Louis:

Advances in Roentgen Diagnosis of Heart Disease: Exhibit demonstrating the anatomic relationships of the heart and great vessels as seen in the frontal, lateral and in the right and left oblique positions; the clinical advantages in using these positions are discussed; the value of roentgen kymograms and of laminagraphs obtained by body section radiography is demonstrated in the roentgen diagnosis of the various types of heart disease; motion picture showing kymography and laminagraphy.

HUBERT B. PEUGNET and FRANK URBAN, Washington University School of Medicine, St. Louis:

Effect of Vitamin C on the Contraction Height of the Frog Heart: Exhibit showing effect of vitamin C on the contraction height of the frog heart; using isolated hearts of Rana pipiens perfused at room temperature with bicarbonate Ringer's solution and vitamin C.

BENJAMIN A. GOULEY, Philadelphia:

Lung Changes Produced by Rheumatic Fever and Their Role in the Development of Rheumatic Heart Disease: Exhibit of microscopic sections of the parenchymal and vascular pulmonary lesions in rheumatic fever; demonstration of the chronic pulmonary lesions seen in association with chronic rheumatic heart disease.

S. A. WEISMAN, University of Minnesota, Minneapolis:

Clinical and Experimental Studies on Quinidine: Exhibit of charts illustrating the length of time quinidine remains in the blood, heart muscle and other organs after intravenous and oral administration; follow-up study on the ambulatory treatment of auricular fibrillation and the method used.

JULIUS JENSEN, St. Louis:

The Heart in Pregnancy: Exhibit of tables and graphs summarizing the present knowledge of the subject of the heart in pregnancy; the various physiologic changes in the cardiovascular system during pregnancy; the effects of the various factors which influence the prognosis and treatment in pregnant women with rheumatic heart disease and other forms of heart disease.

G. E. HALL, University of Toronto, Toronto:

Heart Disease; an Experimental Study: Exhibit depicting (*a*) experimental disturbance in regulation of autonomic nervous system shown by electrocardiograms, photomicrographs and clinical charts of animals with "heart disease" produced by injections of acetylcholine, vagus stimulation, adrenalectomy and the like, with a possible correlation; (*b*) coronary artery reflexes in acute experimental occlusion shown by cleared specimens, mortality tables, diagrams of reflex arc, electrocardiograms and photomicrographs, establishing the presence of a nervous mechanism in the serious effects of coronary occlusion; (*c*) possible clinical interpretation of experimental results shown by cleared heart specimens of human beings of varying ages and a series of cleared dog hearts showing progressive revascularization of infarcted area with corresponding electrocardiograms; photomicrographs showing similar healing process.

MELVIN H. KNISELY, University of Chicago, Chicago:

The Fused Quartz Method of Illuminating Living, Internal Organs for Microscopic Study: Exhibit showing the fused quartz method of illuminating living, internal organs for microscopic study; colored microscopic motion pictures of the capillary circulation in Amblystoma tigrinum brain and in frog lungs, kidney glomeruli, adrenal gland, striated and smooth muscle, and liver, showing that in no two organs is the capillary circulation the same and that the capillary circulation is in each organ integrated with the functioning of that organ.

ST. LOUIS CARDIAC CLUB, St. Louis:

Syphilis of the Cardiovascular System: (For description of exhibit see Educational Classification.)

GRAHAM ASHER, GEORGE WALKER and FRANK HOECKER, University of Kansas, Kansas City:

Lag-Screen Electrocardiograph for the Instant and Continuous Viewing of Electrocardiograms: Exhibit of charts, diagrams and photographs describing the lag-screen electrocardiograph giving the physical principles and clinical uses; demonstration of a lag-screen belt built in an electrocardiograph machine and two forms of separate attachments, also a cathode ray all-electric lag-screen electrocardiograph machine.

COMMITTEE FOR THE STANDARDIZATION OF BLOOD PRESSURE READINGS, New York:

Standard Method for Taking Blood Pressure Readings: (For description of exhibit see Educational Classification.)

J. D. SPILLANE, Massachusetts General Hospital, Boston:

Diseased Hearts and Volumetric Reconstructions: Exhibit of life-size models of diseased hearts illustrating the commoner forms of heart disease and their effects on the size and shape of the heart and its chambers and on surrounding structures; photographs illustrating the method employed in making the models.

AMERICAN HEART ASSOCIATION, New York:

Educational and Exhibit Material of the American Heart Association: (For description of exhibit see Educational Classification.)

CLAYTON J. LUNDY, Rush Medical College, Chicago:

The Electrocardiographic Registration of the Heart in Health and Disease: Exhibit of charts depicting the electrocardiographic registration of the heart in health and disease, especially the normal heart beat, extrasystoles, paroxysmal tachycardia, auricular fibrillation, auricular flutter, heart block, arteriosclerotic heart disease and rheumatic heart disease; motion pictures on these subjects will be shown in an adjoining area.

MOTION PICTURES

Motion pictures on subjects related to heart disease will be shown continuously in an area adjoining the exhibits on heart disease. Among the pictures to be shown will be the following:

GRAHAM ASHER, Kansas City:

Electrocardiograph Readings.

WILLIAM H. STEWART, New York:

Cardiac Cine-Fluorography: Motion pictures of the fluoroscopic image of common cardiac lesions.

CLAYTON J. LUNDY, Rush Medical College, Chicago:

The Normal Heart Beat; Extrasystoles: Six Types; Paroxysmal Tachycardia: Six Types; Auricular Fibrillation; Auricular Flutter; Heart Block: two reels (Includes Bundle Branch Block); Arteriosclerotic Heart Disease: three reels—(a) Coronary Thrombosis, (b) Early Chronic Coronary Arteriosclerosis; Heart Disease, (c) Late Stages of Coronary Arteriosclerosis; Rheumatic Heart Disease: one reel—(a) Early Signs, (b) Late Signs.

EDUCATIONAL CLASSIFICATION

Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than of individuals and which are intended to show progress in the particular activities with which those institutions deal.

These exhibits are not open to medal awards, but a certificate of merit is presented to the best exhibit in the classification.

The exhibits listed under Exhibit Symposium on Medical Education, Hospitals and Licensure also belong in this classification.

ASSOCIATION OF LIFE INSURANCE MEDICAL DIRECTORS OF AMERICA, New York:

Life Insurance Medicine; Procedures and Studies: Exhibit of films and charts illustrating teleoroentgenkymography; normal films together with those showing various types of heart disease; films and charts showing spontaneous pneumothorax; charts showing the efficiency of the Kline test; mortality from hypertension, tobacco and other sources; charts indicating results from sugar tolerance tests.

ST. LOUIS CARDIAC CLUB, St. Louis:

Syphilis of the Cardiovascular System: Exhibit demonstrating the effects of syphilis on the cardiovascular system by pathologic specimens, gross and microscopic illustrations, charts of diagnosis and aids thereto; method of treatment, prognostic and statistical charts; importance as a form of preventable heart disease; public health aspects and relation to syphilitic control.

COMMITTEE FOR THE STANDARDIZATION OF BLOOD PRESSURE READINGS, New York:

Standard Method for Taking Blood Pressure Readings: Exhibit of charts and apparatus showing the standard technic adopted by the Committee for the Standardization of Blood Pressure Readings of the American Heart Association and the Cardiology Society of Great Britain and Ireland; common causes of error in taking blood pressure readings will be emphasized.

AMERICAN HEART ASSOCIATION, New York:

Educational and Exhibit Material of American Heart Association: Exhibit of material including books, pamphlets and leaflets on various phases of cardiovascular disease.

AMERICAN SOCIETY FOR CONTROL OF CANCER, New York:

Diagnosis of Cancer: Exhibit showing a clinic on cancer, with cases of cancer in each booth, showing cancer of the extremities, head, neck and mouth, illustrating standard forms of treatment such as surgical, roentgen and radium and these methods in combination.

MISSOURI CANCER COMMITTEE, AMERICAN SOCIETY FOR THE CONTROL OF CANCER, St. Louis:

Fight Cancer With Knowledge: Exhibit showing factors in a campaign for the control of cancer.

AMERICAN COLLEGE OF SURGEONS, Chicago:

Cancer and Hospitals: Exhibit of charts showing the work of the College on cancer in hospitals.

AMERICAN MEDICAL ASSOCIATION:

Council on Physical Therapy: Exhibit consisting of demonstrations of apparatus pertaining to hearing amelioration; charts on the work of the Council regarding the standardization of audiometers and the investigation of hearing aids.

AMERICAN SOCIETY FOR THE HARD OF HEARING, Washington, D. C.:

Exhibit giving information regarding the prevention of deafness, the conservation of hearing, hearing tests, lip reading and hearing devices; posters and charts emphasizing the four-point program of the Society, viz. prevention, conservation, alleviation and rehabilitation.

BUREAU OF ANIMAL INDUSTRY, UNITED STATES DEPARTMENT OF AGRICULTURE, Washington, D. C.:

Animal Pathology and Parasites: Exhibit includes wax models of specimens showing abnormal conditions with normal conditions for comparison; specimens of ticks and lice; and transparent tube of worm parasites.

BUREAU OF HOME ECONOMICS, UNITED STATES DEPARTMENT OF AGRICULTURE, Washington, D. C.:

Study of Vitamin A Requirements and Vitamin A Intake of Families of Wage Earners: Exhibit of charts visualizing the variations in vitamin storage, vitamin A requirements and carotene requirements of human subjects in parallel with vitamin A intake of the wage earner families; display of publications, small charts and graphs.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS, New York:

The Doctor's Part in Sight Conservation: Exhibit illustrating the various aspects of prevention of blindness and their relationship to the medical profession, together with a presentation of the services which the Society is prepared to extend to the doctor as an individual, as well as to the medical profession as a whole.

MISSOURI STATE MEDICAL ASSOCIATION, COMMITTEE ON CONSERVATION OF EYESIGHT, St. Louis:

Exhibit of charts, displays and pictures showing how the Committee on Conservation of Eyesight of the Missouri State Medical Association is endeavoring to educate the citizens of the state as to the necessity of proper care of their eyes; how a speakers' committee is always able to furnish a speaker and a motion picture for lay audiences with special efforts to appear before junior high and high schools, college and civic clubs, as well as medical societies; exhibits shown at medical and other conventions.

AMERICAN PHARMACEUTICAL ASSOCIATION, Washington, D. C.:

National Formulary Preparations: Exhibit of National Formulary preparations of interest to prescribing physicians; examples of preparations of therapeutic importance representing convenient and satisfactory dosage forms, and of vehicles designed to aid the physician in prescribing attractive and palatable prescriptions.

AMERICAN PHYSIOTHERAPY ASSOCIATION, Chicago:

Exhibit of unusual photographic studies of muscles; residual effect of anterior poliomyelitis; miniature physical therapy department with posters showing photographs made by Harvard Infantile Paralysis Commission; three dimension model of a physical therapy department.

AMERICAN MEDICAL ASSOCIATION:

Bureau of Investigation: Exhibit of charts showing the recent work of the Bureau of Investigation.

AMERICAN MEDICAL ASSOCIATION:

Cooperative Exhibit of the Council on Pharmacy and Chemistry, the Council on Foods, and the Council on Physical Therapy, in conjunction with the Bureau of Legal Medicine and Legislation: Material to illustrate how the new Food, Drug and Cosmetic Act may change some heretofore prevailing practices with which changes physicians should be familiar.

COMMITTEE ON NONSPECIFIC THERAPY OF SYPHILIS, DIVISION OF VENEREAL DISEASES, UNITED STATES PUBLIC HEALTH SERVICE, Washington, D. C.:

Comparative Evaluation of Malaria with Mechanotherapy in the Treatment of Dementia Paralytica: Exhibit of graphic illustrations showing relative effects of two methods of therapy in dementia paralytica on the end clinical results and on the blood and spinal fluid reactions; data forming the basis for the evaluation have been consolidated from the records of ten of the larger clinics of the United States.

AMERICAN HUMAN SERUM ASSOCIATION, Milwaukee:

Human Convalescent Serum: Exhibit of photographs and apparatus used in the collection, preparation and dispensation of human convalescent serum as well as charts showing the results of prophylaxis and treatment following the use of human convalescent serum in various contagious diseases.

CHILDREN'S BUREAU, UNITED STATES DEPARTMENT OF LABOR, Washington, D. C.:

Services for Crippled Children Under the Social Security Act: Exhibit depicting various aspects of the program of services for crippled children developed throughout the country under the

Social Security Act, illustrating location, diagnosis, hospitalization and aftercare of crippled children, and the part which is being played in the work of the official state agencies by physicians and surgeons, public health nurses, social workers and others.

AMERICAN ASSOCIATION OF MEDICAL SOCIAL WORKERS, Chicago:

Exhibit of charts showing centers approved for education in medical social work and distribution of graduates; books, pamphlets and reports of studies on the social component in illness; participation in the teaching social aspects to medical students and others.

MUNICIPAL TUBERCULOSIS SANITARIUM, Chicago:

Municipal Tuberculosis Sanitarium School Survey: Exhibit of charts giving accurate figures of number of children tested, the number found positive by tuberculin (Mantoux) test and subsequent roentgenograms; demonstration of the technic of the Mantoux test.

NATIONAL TUBERCULOSIS ASSOCIATION, New York:

Pulmonary Tuberculosis and Chest Diseases: Demonstrations of roentgen ray films on pulmonary tuberculosis and chest diseases will be made by specialists in this field.

U. S. PHARMACOPEIAL CONVENTION, Philadelphia:

United States Pharmacopeia, Eleventh Revision: Exhibit of pharmacopeial preparations and chemicals and a demonstration of the use of these in prescription practice.

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION, New York, N. Y.:

Exhibit of charts, photographs, case histories and other objects presenting the principles of occupational therapy and the results of such treatment.

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Denver:

Registry of Medical Technologists: Exhibit of charts teaching the importance of employment by hospitals and physicians of properly trained medical technologists; charts giving data regarding approved training schools; descriptive literature; blank forms.

AMERICAN COLLEGE OF CHEST PHYSICIANS, St. Louis:

Differential Diagnosis of Pleurisy with Effusion: Exhibit of roentgenograms of the chest, accompanied by a brief history of each case and with autopsy reports in some cases, illustrating about twenty different types of underlying pathologic lesions of the chest, probably causing the effusion; diagnosis of pleurisy with effusion is an incomplete one unless the underlying pathologic lesion is recognized in the diagnosis.

EXHIBIT SYMPOSIUM ON MEDICAL EDUCATION, HOSPITALS AND LICENSURE

The exhibit symposium on medical education, hospitals and licensure is presented with the cooperation of the Council on Medical Education and Hospitals.

IOWA STATE MEDICAL SOCIETY, Des Moines:

Ten Years of Graduate Medical Education in Iowa: Exhibit of a composite map showing all the courses which have been presented in Iowa during the past ten years; maps showing the progress Iowa has made each year and programs which have been presented; the total enrolments in the courses, the complete activities for the period of ten years, and the details of the courses; programs include the subjects, lecturers and locations of the courses which have been conducted in the state.

OKLAHOMA STATE MEDICAL ASSOCIATION, COMMITTEE ON POSTGRADUATE MEDICAL STUDY, Oklahoma City:

Graduate Teaching in Obstetrics: Exhibit portraying the administration and operation of the two year program on graduate teaching in obstetrics in the state of Oklahoma; colored maps showing locations of teaching centers and location of every registrant; aids used in teaching and pertinent information regarding the courses; pamphlet giving the history and methods of operation of postgraduate medical teaching in Oklahoma since 1925.

MEDICAL SOCIETY OF VIRGINIA, University:

Graduate Medical Instruction in Virginia: Exhibit of maps and charts showing instruction in pediatrics, instruction in obstetrics, statistics on pediatrics and statistics on obstetrics; printed sample programs.

TENNESSEE STATE MEDICAL ASSOCIATION, Nashville:

Educational Program: Exhibit of a chart showing Educational Committee with subcommittees, with maps of Tennessee, letters of appreciation from doctors taking the courses, claiming results to themselves by reason of the instruction, and charts and teaching aids used in the programs; course outlines, forms of letter announcements and mimeographed descriptive pamphlets for distribution.

NORTH CAROLINA STATE MEDICAL SOCIETY, Raleigh:

Graduate Medical Education in North Carolina: Exhibit of descriptive, statistical and illustrated material showing graduate medical education programs of the North Carolina State Medical Society, the North Carolina State Board of Health, the University of North Carolina, Duke University and Wake Forest College from 1929 to 1939.

AMERICAN HOSPITAL ASSOCIATION, Chicago:

Library and Service Bureau: Exhibit of graphs, charts, package libraries, publications, books and literature of hospital interest.

ST. LOUIS CLINICS, St. Louis:

Exhibit demonstrating the activities of the St. Louis Clinics, an organization which holds annual clinical conferences; illustration of the various institutions in St. Louis used for these clinical conferences and including all of the grade A hospitals in St. Louis and those of the two medical schools.

AMERICAN MEDICAL ASSOCIATION:

Council on Industrial Health: Exhibit of posters on principal problems affecting industrial health, present agencies involved in control of industrial hazards, and present status of undergraduate and graduate teaching of industrial hygiene.

AMERICAN MEDICAL ASSOCIATION:

Council on Medical Education and Hospitals: Exhibit featuring the survey of medical education and status of medical colleges; graduate education and continuation courses for physicians; approved residencies in specialties-list and revised essentials; approved internships-list and revised essentials; hospital facilities in the United States; approved schools of laboratory technic; physical therapy and occupational therapy; publications of the Council.

DELAWARE-BLACKFORD COUNTY MEDICAL SOCIETY, Muncie, Ind.:

Middletown Modernizes Medicine; The Indiana Plan as Adapted by the Delaware-Blackford County Medical Society: Exhibit outlining the medical and lay education program as applied by an average sized county medical society; this program is an outgrowth of the Indiana Plan and includes lay education along the lines of preventive medicine and graduate medical education.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES, Chicago:

Exhibit of charts showing results of educational studies made on applicants for admission to medical schools; accomplishment of students listed according to arts colleges in which preparation for study of medicine was made; correlation of scholarship in arts and in medical colleges; analysis of entrance credentials and correlation with work in medical school; comparative accomplishment of men and women students; data on the various activities of the Association of American Medical Colleges.

ADVISORY BOARD FOR MEDICAL SPECIALTIES, Pittsburgh:

Exhibit of charts, graphs and literature describing the work of the Advisory Board for Medical Specialties and of the examining Boards for Certification in medical specialties, including the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, of Dermatology and Syphilology, of Pediatrics, of Psychiatry and Neurology, of Radiology, of Orthopedic Surgery, of Urology, of Pathology, of Internal Medicine, and of Surgery (of Anesthesiology as an affiliate of the American Board of Surgery).

NATIONAL BOARD OF MEDICAL EXAMINERS, Philadelphia:

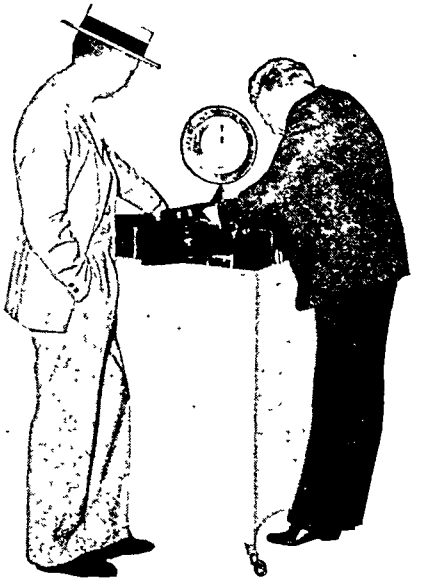
Exhibit of charts describing the work and progress of the National Board of Medical Examiners and a graphic presentation of the results of its examinations.

The TECHNICAL Exposition

A showing by more than 240 Firms

IMPROVED APPARATUS and INSTRUMENTS

LATEST BOOKS • SPECIAL FOODS



NEW REMEDIES

★ To a busy man an opportunity to see a compact, comprehensive panorama of new developments in his field is too important to miss. He realizes the value of a quick check-up on new ideas to guard against overlooking something of definite value. For medical men, the yearly Technical Exposition offers this opportunity.

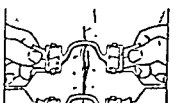
★ Here, in a short five-day span, the huge cornucopia of medical sciences and services will be displayed for the benefit of the physician who comes to the Convention. From the time he sets foot in the huge Convention Hall, until his departure, he will be in lively contact with the vibrant progressive pageant of industry serving the profession. Like milestones of progress, exhibits will highlight new improvements in products or services—forward strides in manufacturing—technical advances of benefit to the doctor.

★ In a true spirit of service, nearly one thousand highly trained men, representing over 240 firms, will be on hand to help bring the exhibits to life—make them a dramatic summary of the year's progress in pharmaceuticals, biologicals, medical books, instruments, apparatus, electrical equipment, dietetic products, and other specialized articles and services. The physican can feel free to inspect all exhibits without any feeling of obligation.

★ Thus, St. Louis, "the city of a thousand sights" will add a thousand educational stimuli through the medium of the Technical Exposition. From 8: 30 A. M. to 6: 00 P. M. each day and until noon on Friday, the Exposition will be in full activity. By visiting the exhibits before, after, or between meetings, the physician will not only add to his store of knowledge, but will meet old friends and make many new ones.

APPARATUS AND INSTRUMENTS

A. S. ALOE COMPANY



With its home offices in St. Louis, the Aloe Company is enabled to show an elaborate exhibit, actually an entire aisle comprising complete equipment for the physician and his office. Featured will be the new Aloe X-Ray, designed expressly for every necessity in general practice; Aloe Steeline Furniture; the new Aloe Short Wave Diatherm; and complete clinical laboratory equipment. Booths 68, 69, 70, 71 and 72.

AMERICAN HOSPITAL SUPPLY CORP.

At Booth 133 you will see new improvements in equipment for vascular gymnastics and intermittent venous occlusion. There will be periodic demonstrations of intravenous therapy, illustrated discussions on prevention of peritonitis, reports on the latest motorless suction siphonage units, and the nasal administration of oxygen by a device which properly humidifies oxygen. Be sure to save at least 15 minutes to investigate these exhibits.

AMERICAN MEDICAL SPEC. CO., INC.

In Booth 159 will be found four interesting and outstanding specialties: (1) the Wound Bridge and its applications; (2) the Amsco Oscillometer which takes blood pressure without need of a stethoscope; (3) the Flexo Pessary and (4) the A.B.C. Zipper Blood Pressure Cuff. Representatives will be glad to demonstrate all of these items.

AMERICAN SAFETY RAZOR CORP.

Registered nurses will be on hand to welcome visitors to the A. S. R. Surgeon's Blades exhibit. If you want to know more about these keen, uniform blades, be sure to visit Booth 223 and talk to Miss Stewart and Miss Bard, who, from personal experience and observation can answer your questions. They will gladly explain the various uses of the blades—9 types in all, to suit every need.

(Continued on next page)

AMERICAN STERILIZER COMPANY

This exhibit, occupying Booth 4 and a portion of Booth 3, will show the visitor operating tables, surgical lights, and sterilizers of latest design.

BARD-PARKER COMPANY, INC.

Among the Bard-Parker products exhibited at Booth 186 will be Rib-Back Blades, Renewable Edge Stainless Steel Scissors, Lahey Lock Forceps and Hematological Case for obtaining blood samples at the bedside.

BECTON, DICKINSON & CO.

In Booths 206, 207, 208 and 209 Becton, Dickinson will again provide a demonstration of glass blowing as applied to the making of all glass hypodermic syringes and fever thermometers. In addition to this, complete displays of instruments associated in the various fields of practice will be available to all physicians.

CAMERON SURGICAL SPECIALTY CO.

The new Cameron Projectoray and Lempert-LeMee Headlite will be demonstrated in Booths No. 55 and 238. Latest developments in electrically lighted diagnostic and operating instruments for all parts of the body will be shown. Of special interest will be the new inexpensive office model Radio Knife, Combination Spark-Gap & Tube Electro-Surgical Unit, and other electro-surgical units for cutting, coagulating, desiccation and fulguration in all sizes from the office model up to the hospital unit.

E & J MANUFACTURING CO.

An unusually interesting illustration of respiration during mechanical resuscitation will be offered by E & J Company's exhibit of "breathing mother and baby," Booth 266. Behind the transparent "chest wall" of the "mother" one will be able to observe rhythmic rise and fall of the "lungs" and the excursion of the "diaphragm" during resuscitation treatment. Plan to see this educational display.

FOREGGER COMPANY, INC.

A new type of individual flow meter apparatus for anesthesia, helium and oxygen therapy equipment, resuscitation apparatus and a complete line of intratracheal apparatus and accessories will be on display at the Foregger Booth, No. 53. The helium apparatus to be shown will be of interest not only to the hospital personnel and anesthetist but to the general practitioner as well inasmuch as it is suitable for office and bedside use.

HAMILTON-SCHMIDT SURGICAL CO.

Specialties of several manufacturers will be shown by Hamilton-Schmidt, local representatives, at Booth 33: Physical therapy equipment of Burdick Corp.; office equipment of Hamilton Mfg. Co.; Bard-Parker and Stille instruments; and Sterisol intravenous ampoules.

KITCHEN KATCH-ALL CORP.

A simple, but efficient All-Nite Vaporizer which provides plain or medicated vapors for periods up to 12 hours, will be demonstrated at Booth 100. Also a Miniature Hospital Formula Room Outfit for baby at home will be shown.

MACGREGOR INSTRUMENT COMPANY

A complete line of Vim products will be displayed in Booth 92. Included in this unusual exhibit will be a full line of Vim Needles of Firth-Brearley Stainless Steel, Vim Green Emerald Syringes and some new Vim specialties. In addition, the MacGregor Instrument Co. will show a complete assortment of the English-made Iron Arm Surgeons' Needles.

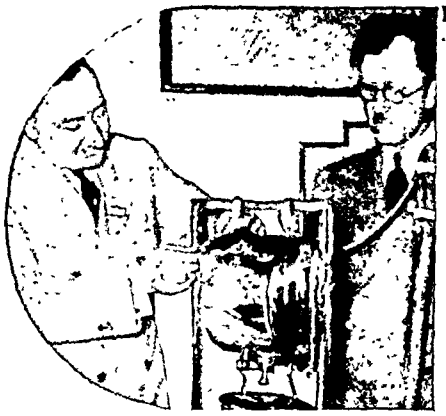
V. MUELLER & COMPANY

Such items of unusual interest as the new Cope-deMartel clamp, Devine and Ochsner-DeBakey spur crushers, simplified Scuderi-Callahan fracture instruments, and Dr. Dimitri's new Cataract Suction Disc are a few of the many highlights of V. Mueller's big exhibit in Booths 38 and 39. In addition to the comprehensive instrument display, the Herb-Mueller Ether-Vapor and Vacuum Apparatus and other modern equipment will attract much attention.

OHIO CHEMICAL & MFG. CO.

In Booth 167 will be found a complete line of the well-known Heidbrink Kinetometer Gas Machines and Oropharyngeal Outfits, in addition to other types of therapy equipment which are especially adapted for hospital use. There will also be a full display of Ohio equipment, supplies and gases in which there are some new developments which merit investigation.

PELTON & CRANE COMPANY



In Booth 280, Aisle A, Pelton and Crane will exhibit all models of standard 3-Speed and Super-Automatic Sterilizers, both table models and cabinet outfits. Also on display will be Pelton cuspidors and operating lights. The exhibit will be in charge of Mr. J. L. Bunch, who will welcome your questions and appreciate your visit.

GEORGE P. PILLING & SON CO.

The Miller-Abbott double lumen tube for small intestinal intubation will be included in the Pilling exhibit, Booth 183; also the Crutchfield tongs for treatment of the fractured dislocations of the cervical vertebrae; the armamentarium of Dr. Max Halle used in nasal surgery; the Kasper headlight; the bronchoscopic instruments as made for and used by the Chevalier Jackson Clinics; thoracic instruments; and new and important instruments in general and rectal surgery.

PROMETHEUS ELECTRIC CORP.

The complete Prometheus line of medical and surgical products will be on display at Booth 218. Among the items shown will be pressure sterilizers, stainless steel instrument sterilizers, hospital equipment and infra-red lamps. Various improvements and re-styling of items make this one of the most interesting of Prometheus exhibits.

WILMOT CASTLE COMPANY

Among the items to be shown by the Castle Company, Booth 197, will be a display of modern surgical lights. The representatives will be glad to demonstrate the ease with which these lights can be positioned and adjusted.

CLAY-ADAMS COMPANY

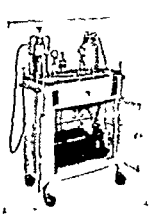
New developments in centrifuges, anatomical models, charts, skeletons, obstetrical manikins, surgical and laboratory instruments, and specialties will be shown in Booth 114. A feature of the display will be a new low-priced Bay-Jacobs miniature Obstetrical Manikin made up of an aluminum female pelvis and fetal skull. The centrifuge exhibit will include a new arrangement.

CRESCENT SURGICAL SALES CO., INC.

Convention visitors are invited to call at Booth 61 and see just how Crescent's Mikro-Keen and Rigipoised blades, with forty years' experience back of them, are made. Free samples will be available for the asking.

DEVILBISS COMPANY

The complete DeVilbiss line of atomizers, steam vaporizers and nebulizers will be on display at Booth 163. Specially featured in the exhibit will be illustrations based on x-ray research, graphically showing the coverage afforded by the atomizer in application of solutions to the nose and throat. Copies of the illustrations for reference may be secured from the DeVilbiss representative in charge.



SAFETY GAS MACHINE CO., INC.

The McCurdy & Augustana Models equipped with their new improved CO_2 Absorber unit, which increases the efficiency and lowers the breathing resistance, will be shown in Booth 107. The exhibit will be in charge of an experienced anaesthetist who will be glad to advise on anaesthetic department problems.

SCANLAN-MORRIS COMPANY

Several new items of surgical equipment will be included in the Scanlan-Morris exhibit, Booth 224. Their latest major operating table will be demonstrated, together with the famous Operay Multibeam and Surg-O-Ray surgical lights. A clinic sterilizing outfit, consisting of autoclave and 3-gal. water sterilizer, will be on display. Visitors will also have opportunity to inspect samples of genuine Swedish made Stille instruments.

J. SKLAR MANUFACTURING CO.

The Sklar exhibit, Booth 2, will feature new suction and pressure apparatus, including the Improved Tompkins Portable Rotary Compressor, the DeLuxe Tompkins, the new Imperatorl Apparatus for ear, nose and throat work, Ralks' Ideal Unit and Moorhead Unit for office and clinic, and the new, improved, heavy duty hospital model of the Bellevue Suction and Pressure Unit.

STORZ INSTRUMENT COMPANY

In Booth 26 the Storz Instrument Company will show, among other new models of instruments, their new and improved American made stainless steel Fulforce Adenotome A wide selection of instruments and equipment for the eye, ear, nose and throat specialist will be on display Mr Eric Storz and Mr Fred S Watson, who will be in attendance, will be glad to discuss these instruments and demonstrate the line of Gomco Surgical Pumps

MAX WOCHER & SON COMPANY

True to tradition, Wocher's will feature several brand-new items of interest to medical and surgical men, at Booths 135 and 143 Foremost among these is the new Ries-Lewis Explosion-Proof Operating Light, which banishes fear of explosion due to faulty lighting equipment Worthy of note is the fact that this light bears the seal of approval of the Underwriters Laboratories In addition, there will be shown the Mont R Reid operating table and other instruments and equipment

ZIMMER MANUFACTURING COMPANY

The complete line of Zimmer orthopedic equipment will be shown in Booth 289 The exhibit will be an interesting one for any surgeon who handles fractures, inasmuch as the firm has specialized in stainless steel bone instruments Splints of improved design, stainless steel bone plates and screws, Smith-Petersen nails and accessories, hyper-extension frames, fracture bed and orthopedic braces will be featured

DIAGNOSTIC EQUIPMENT

BECK-LEE CORPORATION

Booth 12 should be of interest to all physicians Here, Beck-Lee will show both portable and mobile models of quartz string galvanometer electrocardiographs, designed by Charles F Hindle A visit to their booth would be instructive and valuable to physicians interested in complete and accurate cardiac diagnosis

CURVLITE PRODUCTS, INC

Some of the most widely publicized medical and dental instruments of the last decade will be on display at the Curvlite exhibit, Booth 148 Demonstrations will show how Curvlite instruments permit the transmission of light directly through the instruments themselves into the operative or diagnostic area—cold, brilliant light without interference with the operator

ELECTRO SURGICAL INSTRUMENT CO

At the Electro Surgical exhibit, Booth 109, there will be shown a complete line of electrically lighted surgical instruments, including the improved Braasch-Bumpus resectoscope, Bue, Lynch, Tuttle, and Paulson proctosigmoidoscopes, Jackson, Israel and Lynah bronchoscopes, Holmes nasopharyngoscopes and antroscopes, transilluminators, Braasch and Davis cystoscopes, urethroscopes, and rheostats

FROBER-FAYBOR COMPANY

Among the instruments to be shown by Frober-Faybor at Booth 11 will be their low-priced Visual Photometer, Visual Aptometer, and several Bio-Photometer models —all clinical instruments for determining light thresholds in relation to light, sight, visual purple and vitamin A A research model of a new Audiometer for determining sound thresholds and a Frober-Faybor Colorimeter (rapidly gaining use in running blood tests) will also be on display

GASTRO-PHOTOR LABORATORIES

The new, improved stomach camera, an outstanding development of modern diagnostic apparatus, will be shown at Booth 111 A large number of normal and pathological gastrophotographs will be on display

GRADWOHL LABORATORIES

An exhibition of Gradwohl reagents and equipment for laboratory purposes will be found at Booth 119 Special attention will be devoted to the well-known Giemsa stain for hematological work Blood grouping tests by means of potent testing sera will also be emphasized, and testing sera of high degree of potency will be shown

HERZ-LASKER CORPORATION

At Booth 296 visitors will have opportunity to inspect the Offner Electrocardiograph, a revolutionary innovation in cardiography, which records heart currents directly in ink on a moving chart so that no dark room development is needed The machine can also be used to record the heart sounds and in addition serves as an electro stethoscope Other items to be exhibited are the Weiss Sinusoidal Galvanic Machine, the Erlanger Ionization Unit, and the Mittelmann Dosage Meter

JONES METABOLISM EQUIPMENT CO

The Jones Motor Basal metabolism apparatus will be featured in Booth 64 Visitors will be interested in demonstration of a special feature of this unit—it contains no water and requires no calculation in the determination of the basal metabolic rate

THE KELLEY-KOETT MFG CO, INC

In Booths 225, 246, 247 and 248, Keleket will display new x-ray apparatus providing for complete radiographic and fluoroscopic diagnosis A new mobile unit offering a complete 90 Peak KV 30 MA on wheels for will be demonstrated) be on display a complete self-contained diagnostic x-ray unit which offers facilities for fluoroscopy, radiography and Potter Bucky diaphragm radiography in three positions

LAMOTTE CHEMICAL PRODUCTS CO

LaMotte Blood Chemistry Outfits will be exhibited in Booth 79 Recent developments to be shown include the LaMotte outfits for determining sulfanilamide in blood and urine and the LaMotte Falling Drop Densiometer for determining blood proteins Information will also be available concerning the determination of sulfapyridine in blood and urine

E LEITZ, INC

Ortholux, a modern research microscope in a reversed type of stand with built-in permanently aligned illumination system and a new universal type of substage, will be exhibited in Booth 62 Medical microscopes for bright and dark field, various microtomes, projectors, photomicrographic equipment (including the Panphot—a combination universal microscope and reflex camera) and Leica cameras will also be gladly demonstrated

TAYLOR INSTRUMENT COMPANIES

The Tycos exhibit, Booth 151, will display an interesting working model showing the inside of a Tycos Aneroid Sphygmomanometer and demonstrating how metal diaphragm chambers operate the Tycos, instead of a coil spring Don't miss the action display showing how a Mercurial Manometer becomes inaccurate when tipped slightly, such as when resting upon a bed Be sure to see also the new, flat glass Binoc fever thermometer and the Pavaex "glass boot" for treating circulatory diseases

WELCH ALLYN COMPANY

At the Welch Allyn Booth, No 136, will be seen the latest advances that have been made in the manufacture of laryngoscopes, the demand for which in cases of asphyxiation is growing throughout the country, and also the new complete endoscopic sets with telescopic attachments which have added remarkably to visualization The newest features in eye, ear, nose and throat instruments will also be incorporated in the instruments shown at this booth

DIETETIC PRODUCTS

AMERICAN CAN COMPANY

All registrants at the Convention are cordially invited to call at Booths 47 and 48 where information will be available concerning those aspects of commercially canned foods which are of greatest interest to the medical profession Literature on canned foods, designed specifically for the physician's use, will also be on display

BEST FOODS, INC

Doctors are invited to visit Booth 109 and taste New Nucoa, a wholesome spread for bread—a delicious, easily digested and nourishing vegetable margarine The exhibit, featuring the addition of Vitamin A to the product, will also display composite results of recent assay work conducted by three independent food laboratories This will be an excellent opportunity to become acquainted with the digestibility of Nucoa, which has been demonstrated by work on human beings

CARNATION COMPANY

In the Carnation exhibit in Booth 181 will be displayed an interesting model of the famous Carnation Milk Farms where high producing stock is developed to improve the dairy herds supplying the many Carnatio . . The work of the " in supervising r the scientific processin . rnation Milk will be interestingly shown also

CEREVIM PRODUCTS CORPORATION

Refresh yourself and really enjoy the Convention. Stop at the Cerevim exhibit, Booth 6, periodically for a free, nourishing lunch and energy pick-up—all you want of Cerevim and milk. Ask to see the new, modern treatise [illegible], "The Dietary Requirements of Laboratory Guinea Child." It contains a complete dietary [illegible] from infancy through adolescence, and has a hard-cover binding suitable for a reference library.

CEROPHYL LABORATORIES

A cordial invitation to visit their Booth, No. 112, is extended by Cerophyl Labs. (a division of American Dairies, Inc.). Here you will find on display the new development, Cerophyl, a natural and rich source of Vitamin A, B Complex, C, the grass juice factor, and the newly discovered Vitamin K. Representatives will be on hand to discuss Cerophyl, acceptance of which by the Council on Foods was announced in the J. A. M. A. of February 25, 1939.

HAROLD H. CLAPP, INC.

As originators of commercially prepared strained and chopped foods, Clapp will feature this year three new additions to their line of chopped foods for older babies. These new products, called Junior Dinners, are composed respectively of beef, lamb, and liver combined with selected vegetables and designed to provide the young child with hearty, balanced main dishes. Booth 21.

shown in the new drip grind as well as regular grind. Also Kaffee Hag, another fine blend of decaffeinated coffee, will be served. Other General Foods products of interest to physicians will be on display.

FOLEY MANUFACTURING COMPANY

The Foley Strainer for baby foods (Foley Food Mill) which mashes all cooked vegetables and fruits fine enough for the smallest baby and all smooth diets will be shown at Booth 15. You are invited to call and see how efficiently and economically foods can be prepared the Foley way.

GERBER PRODUCTS COMPANY

The new Gerber Cereal Food will be shown at Gerber's Booth, 211. Samples and professional literature about this cereal product, as well as the other Gerber baby foods, will be available.

HAWAIIAN PINEAPPLE COMPANY, LTD.

The Hawaiian Pineapple Company's exhibit, Booth 265, will feature the Hawaiian background distinctive of its products. Dole Pineapple Juice will be served to all visitors of the booth, and interesting dietetic and recipe material featuring the varied uses of Dole Products, will be distributed.

which are being fed to infants as young as one or two months of age. The display will include photomicrographs comparing textures of solid foods, and roentgenograms comparing their digestion.

M & R DIETETIC LABS., INC

Similac, a completely modified milk for infants deprived of breast feeding, will be displayed by M & R Dietetic, Booth 241. Qualified representatives will gladly explain the value of the zero curd tension of Similac as it applies to both normal and special feeding cases.

MEAD JOHNSON & COMPANY

Several new products will be featured at the Mead Johnson booths 15, 16, 50, 198 and 199. In Room 15-A they will show several new motion pictures. They have made part of this large room available for an art exhibit by the American Physicians' Art Association.

MELLIN'S FOOD COMPANY

At Booth 83 opportunity will be offered for a discussion of the application of Mellin's Food in the feeding of infants whose individual condition sets them apart from so-called normal babies, and whose diet needs to be adjusted in a manner calculated to correct digestive disturbances

CHICAGO DIETETIC SUPPLY HOUSE

Physicians who call at Booth 123 will learn how diabetic diets can be interesting and varied the year around. Here they will be invited to see and taste some of the many canned fruit and juice items packed without sugar by Chicago Dietetic Supply. Here, too, they may learn the answer to patients' dessert problems by seeing a wide variety of sugar free desserts. Competent people will be in attendance.

CORN PRODUCTS REFINING CO.

At Booth 36, the special feature of the Corn Products exhibit will be Dextrose (Karo Brand) as an efficient food energy sugar. Dextrose (Karo Brand) is a new development of this Company's Research Department. Karo (Blue and Red Label), two other well established products with which you are familiar, will also be a part of this exhibit.

DIETENE COMPANY

A special purpose low caloric food that takes the counting out of calories, will be exhibited at Booth 11. All physicians are invited to stop and learn why Dietene is sometimes called "The Modern Diet Kitchen in a Package." Representatives will explain the Dietene regime by which patients can subsist on a low calorie diet and at the same time be protected against deficiencies of important food factors.

GENERAL FOODS CORPORATION

While at the Convention, stop at Booth 138 and have a cup of delicious Sanka Coffee, a choice blend of Central and South American coffees, from which 97% of the caffein has been removed. Sanka will be

H. J. HEINZ COMPANY

Heinz Junior Foods, a new variety for older babies, will be on display in Booth 126. The Heinz representative will be on hand ready to give information concerning this new product, as well as the Heinz Strained Foods on display. Visitors who register at the booth will be sent helpful literature.

HILKER & BLETSCH COMPANY

A new vitamin food product recently accepted by the Council on Foods—Vitamin B1 Wafer (V-B-W) will be exhibited in Booth 142. The wafer, which contains 100 International units by both biological and chemical assay, will be featured for reducing diets and other therapeutic diets inadequate in vitamin B1. Included in the exhibit will be the delicious Vitamin C Beverage (V-C-B) which contains approximately the same amount of vitamin C and caloric content as fresh orange juice.

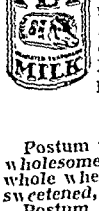
IRRADIATED EVAPORATED MILK INST.

Information and advice on infant feeding, special diets, milk allergy, and many other important uses of irradiated evaporated milk will be presented at Booth 284. Technical booklets on infant feeding and reprints of clinical research, also free copies of "The Story of Irradiated Evaporated Milk," a new book answering questions about this product, its nutritive value and uses, will be available.

LIBBY, McNEILL & LIBBY

You are cordially invited to visit Booth 171 and see the exhibit of Libby's specially Homogenized Foods for Babies, single vegetables as well as combinations of vegetables, fruits and cereal, and soup,

NATIONAL DAIRY COUNCIL



A new and timely exhibit with central theme, "You Need Vitamins Every Day—Get Them From the Foods You Eat," is to be presented in Booth 288. Illuminated transparencies in natural color picture food sources of each of the vitamins. A balanced meal pattern based on a moderate cost adequate diet will show the importance of dairy products in everyday meals

NESTLE'S MILK PRODUCTS, INC.

Nestle's will have a very attractive exhibit in space 215, where Lactogen, Hylac and Nestle's Food will be on display. All physicians interested in infant feeding are cordially invited to visit the Nestle booth

PET MILK SALES CORPORATION

An actual working model of a milk condensing plant in miniature will be exhibited at the Pet Milk Booth, No. 191. This exhibit offers an opportunity to obtain information about the production of irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the exhibit.

POSTUM EXHIBIT

Postum will be served at Booth 82. This wholesome cereal beverage, made from whole wheat and bran, roasted and slightly sweetened, will be exhibited in two forms —Postum Cereal, made like coffee, and Instant Postum, made instantly in the cup or pot. Visitors to this booth will find that served hot or iced, Postum is delicious, economical, and easy to prepare. Postum-Made-with-Milk is an easy way to keep milk interesting.

SCIENTIFIC SUGARS CO.

Specialties in the field of infant diet materials and in Vitamin B Complex therapy will be featured in the Scientific Sugars Booth, No. 46. The firm will show a product made by the aqueous extraction of yeast but substantially free from yeast cells, fats, resins, and inert materials present in dried yeast. Physicians will find that the product is palatable, readily miscible with fruit juices, and excellent to use as a vehicle for iron compounds and other medications. The milk modifier, Cartose, will also be on display.

S.M.A. CORPORATION

At Booths 120 and 275 two beautiful new displays featuring S.M.A. and associated infant feeding prep- [illegible] specialties developed in the S.M.A. laboratories. Be sure to stop at this exhibit for an interesting chat.

STOKELY BROTHERS & COMPANY

The showing of Stokely's Baby Foods, at Booth 276, will afford opportunity to learn more about their comminuting process, particularly designed to produce a smooth, uniform texture and retain the natural color and garden-fresh flavor of the fruits and vegetables. Full details concerning this process, as well as the products, will be available at the booth.

VEGEX, INCORPORATED

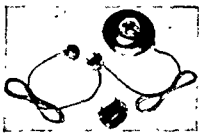
The results of feeding the whole vitamin B complex will be shown at the Vegex exhibit, including yeast extract and liver extract feedings, separately and together. The series will include thiamin, riboflavin and nicotinic acid fed separately and together with yeast and liver extracts. Vegex, served as a drink and with butter as a sandwich spread, will give an appetizing delight to physicians stopping at the exhibit. Booth 96.

VITEX LABORATORIES, INC.

As usual, those attending the meeting can obtain refreshing drinks of vitamin D milk served at the Vitex milk bar. Booth 110.

HEARING AIDS

DICTOGRAPH PRODUCTS CO., INC.



At Booth 274 will be displayed the Acousticon, which brings custom-fitted hearing to your deafened patients, through the Audogauge, which selects the assembly best suited to compensate for hearing [illegible] t to otologists [illegible] thod embody- [illegible] whereby, as a [illegible] the correct vacuum tube wearable portable Acousticon can be fitted to the most difficult case.

SONOTONE CORPORATION

An exhibit of instruments and methods used in fitting electrical hearing aids, including the New Sonotone Continuous Tone Audiometer—a 1939 development—and the Sonotone Audioscope, as well as bone and air conduction hearing aids, will be shown in Booth 156. Also the new Sonotone Audiometer for group testing of school children will be demonstrated. Doctors interested in hearing problems are especially invited to receive a copy of new book on hearing aids.

GRAYBAR ELECTRIC COMPANY, INC.

As national distributors of Western Electric Scientific Equipment, Graybar will feature instruments of interest to the medical profession such as the new Ortho-Technic Hearing Aid, both bone and air conduction, the 4B and 6A Audiometers and the Electrical Stethoscope. Attention will be focused on a map showing the zoning of the 82 Graybar Houses in relation to a nationwide service. Space 149.

MAICO COMPANY, INC.

The widely-used Maico professional audiometer used by otologists in hearing tests and a simplified low-priced model audiometer for public health, school, and general work will be exhibited at Booth 281. Also on display will be amplifying electro-stethoscopes and the Ruckmick Affectometer, which can be used as a lie detector or to measure emotional stability.

F. A. DAVIS COMPANY

For your special pleasure it is suggested that you relax at Booth 219 and examine these new Davis Company books: Reimann's "Treatment in General Medicine," with its new unique up-keep service; Bland's "Practical Gynecology"; Goldberg's "Clinical Tuberculosis"; Delario's X-ray and Radium Therapy"; Lederer's "Ear, Nose and Throat"; Blum's "Pediatric Symptomatology and Diagnosis" and Bland's "Practical Obstetrics."

PAUL B. HOEBER, INC.

New books to be included in the Hoeber exhibit, Booth 91, are Reynolds' [illegible] m's [illegible] nt- [illegible] nd [illegible] ical [illegible] hi- [illegible] of [illegible] ets of Alvarez' new "Mechanics of the Digestive Tract" and of Ewalt, Parsons, Warren and Osborne's "Fever Therapy Technique" will also be shown.

LEA & FEBIGER

At Booth 89 Lea & Febiger will exhibit the following new works: Witherspoon's "Clinical [illegible] y," Eller on "Tumor [illegible] ris, Lachmann and [illegible] natomy," Haden on [illegible] on "Elementary Anatomy [illegible] ," Spaeth on "Ophthalmic [illegible] on "Fractures and [illegible] on "Refraction." New editions will include Kanavel's "Infections," and Brown's "Oral Surgery." The exhibit will be in charge of Mr. Leo A. Cleary.

MEDICAL BOOKS

D. APPLETON-CENTURY COMPANY

The entire line of Appleton-Century medical works will be shown in Booth 236, including the thirteen volume "Practitioners Library of Medicine and Surgery" edited by George Blumer; the set of "Postgraduate Surgery" edited by Rodney Maingot; and the new 13th edition of Osler's "Principles and Practice of Medicine" with a new editor, Henry A. Christian. Many new volumes will be shown, such as "The Fundamentals of Internal Medicine" by Wallace M. Yater, and "Gross Anatomy" by A. Brazier Howell.

P. BLAKISTON'S SON & CO., INC.

Their complete list of medical texts and references, including the books published since the last convention, will be found in the Blakiston exhibit, Booth 65. Two books of particular interest are: Robinson's "Practi[illegible] Marie's *Spanish* [illegible] the latter designed to be distinctly helpful in clinical investigations and research. The exhibit will be in charge of Messrs. H. T. Turner and E. R. Stetson.

CHICAGO MEDICAL BOOK COMPANY

The display at Booth 49 will present a complete assortment of all the latest medical books of all the publishers, including many new American and English monographs to be seen nowhere else. Here, under one exhibit, you can examine at your leisure all of the recent books. Don't fail to visit this most interesting exhibit.

J. B. LIPPINCOTT COMPANY

Among the newer Lippincott publications on display will be Thorek's "Modern Surgical Technic" and Kracke's "Diseases of the Blood and Atlas of Hematology" from which illustrations are being displayed at the World's Fair Medical Exhibit. Other important new works include: Rigler's "Outline of Roentgen Diagnosis," Barborka's "Treatment by Diet" and Imperatori's "Diseases of the Nose and Throat." Booth 1.

MACMILLAN COMPANY

The results obtained from sulfanilamide and sulfapyridine therapy in bacterial infections have centered attention on these new drugs. At the Convention in St. Louis the Macmillan Company will have on display the forthcoming book on this subject by Perrin H. Long and Eleanor A. Bliss, nationally known authorities. Also on exhibit will be many other new medical publications. Booth 59.

L. S. MATTHEWS & CO., INC.

Booth 43 will exhibit a comprehensive stock of the best and latest standard medical books, with some curious items and antique volumes in medicine, and a fine collection of reproductions of famous paintings on medical subjects by eminent artists. Get acquainted with the Matthews trade-in plan. Your call at the booth will be appreciated.

C. V. MOSBY COMPANY

In Booth 101 will be shown the following important new medical books by Mosby: Campbell's "Operative Orthopedics," tenth edition of Sutton's "Diseases of the Skin," the new Brickel "Surgical Treatment of the Hand and Forearm In-

fections," Behan's "Cancer," second edition of Gradwohl's "Clinical Laboratory Methods and Diagnosis," and the new second edition of Meakins' "Practice of Medicine." About 150 other standard and currently popular volumes will complete the display.

OXFORD UNIVERSITY PRESS

On display in Booth 117 will be several new Oxford books covering physiology of anesthesia, clinical electrosurgery, silicosis and asbestosis, carbon monoxide asphyxia, orthopedic appliances, shock and related capillary phenomena, craniocerebral injuries and the well known "Oxford Loose-Leaf Medicine," with Oxford monographs on diagnosis and treatment.

W. B. SAUNDERS COMPANY

In Booths 66 and 67 will be shown a complete line of the Saunders books, among them many new books and new editions, including Callander's "Surgical Anatomy," the 1939 *Mayo Clinic* Volume, Wolf's "Endocrinology," Fluhmann's "Menstrual Disorders," Pelouze's "Gonorrhea," McNally's "Medical [illegible] icology," Murphy's [illegible] trow and Trumper's [illegible]."

SURGERY, GYNECOLOGY AND OBSTET.

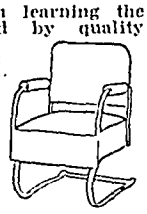
"T[illegible] employed in an in[illegible] of the pages of [illegible]ons by Surgeons," its superb printing and illustration, and

OFFICE FURNITURE

W. D. ALLISON COMPANY

In Booth 216 will be shown a representative display of fine physicians' wooden furniture by Allison. Many improvements have, of course, been added since the last convention in San Francisco. It will be of interest to you to see this equipment.

ENOCHS MANUFACTURING CO.



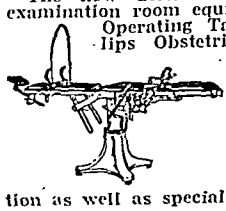
While at the Convention it will pay you to spend a few moments inspecting the latest offerings in fine furniture for physicians' offices. At the Enochs Booth, No. 56, will be shown complete office suites designed to meet the needs of the general practitioner or the specialist. In attendance will be an office planning expert who will be glad to help you with your arrangement problems.

HAMILTON MANUFACTURING CO.

In keeping with the present trend toward new and modern professional furniture, Hamilton will feature its newest group, the Nu-Tone Suite. This is an over-size Deluxe set of furniture that provides extra conveniences and extra comforts. The table which will be shown is 3" wider and 4" longer than the ordinary table with a massive effect that helps to establish a tone of dignity and professional restraint in any office. This new Hamilton furniture will be on display in Booths 211 and 215.

ROYAL METAL MANUFACTURING CO.

If you are interested in learning the many advantages afforded by quality chromium furniture for reception rooms and offices you will want to take time for a visit at Booth 40. Here, in keeping with the demand for this type of furniture, an entire line Royalchrome for office and reception room will be shown. A plan will be made for your particular needs without obligation.



PHILADELPHIA HOSP. SUPPLY CO.

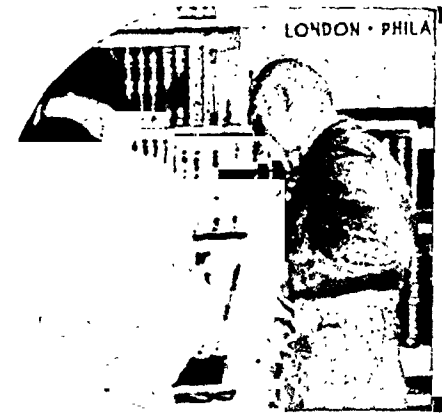
At Booth 298, the Meth Manufacturing Co. and distributor, Philadelphia Hospital Supply Co., will show a new suite of physician's wood furniture in Burl walnut, which has not been shown in its entirety at any medical convention to date. There will also be on display two other suites of physician's furniture, custom built, of genuine American walnut.

SHAMPAINE ASEPTIC STEEL FURN. CO.

The new Steelux line of physicians' examination room equipment, the Century Operating Table, and the Phillips Obstetrical Table will be featured in Booths 30 and 31. The new *Martin Table*, especially designed for rectal work, will be demonstrated with regard to its adaptability to all types of general examination as well as specialized work.

OPTICAL INSTRUMENTS

AMERICAN OPTICAL COMPANY



This exhibit, in Booths 261 and 262, will feature two of the firm's newest instruments, the Additive Phoroptor which provides three points of vital interest to users —prescription accuracy, ease of operation, and patients' comfort—and the Adaptometer, which provides a method of determining the presence of night blindness. Representatives will demonstrate how it permits a quick and reliable differentiation between normal and abnormal adaptation cases.

KEYSTONE VIEW COMPANY

The Keystone exhibit, Booth 217, will feature the Synoptiscope, for strabismus diagnosis and training. Also on display will be the Tel-Eye-Trainer, which is particularly adapted to post-operative fusion training and asthenopia due to faulty eye coordination other than strabismus. Other exhibits will include Keystone's home training materials including the Correct-Eye-Scope, the Eye Comfort Stereoscope and accessories.

CARL ZEISS, INC.

At Booth 175 a collection of Zeiss microscopes, including the latest models, and accessories, will be featured. Camera attachments for photomicrography, as well as Contax Cameras for medical and general photography, will also be shown. Ophthalmic equipment, such as slit lamp outfits, perimeter, retinal and anterior segment cameras, test sets for contact lenses, etc., will be on display. Demonstration by experienced technical representatives and information will be gladly furnished.

UNIVERSITY PRESSES

Booth 178 will display books and journals from the following university presses: University of Chicago; Columbia University; University of Minnesota; University of Pennsylvania; Princeton University; Stanford University; Yale University; and Collegiate Press. A cordial invitation to examine the publications on display is extended to all visitors.

WILLIAMS & WILKINS CO.

As publishers of the famous William Wood books, exhibit 102 will include advance copies of new editions of Stedman's "Medical Dictionary" and May's "Eye." Important new books, such as Fomon's "Traumatic and Plastic Surgery," Yeomans' "Sclerosing Therapy," Cowdry's "Problems of Ageing," and new editions of Allen's "Sex and Internal Secretions," Harrison's "Failure of Circulation," with 200 other new and standard books and periodicals will complete the showing.

AMERICAN MEDICAL ASSOCIATION

The journals, pamphlets, reprints and books published by the A. M. A. will be shown at Booths 127 and 150. In conjunction with this exhibit there will be a showing of "Hygeia," The Health Magazine, at one end, and the state medical journals of the Cooperative Medical Advertising Bureau, at the other end. The "American Medical Directory," "Index Medicus" and other well-known A. M. A. publications will be on display.

SPENCER LENS COMPANY

The Spencer Lens exhibit will feature medical microscopes, equipped for bright field and dark field work; also for blood counting with the Bright-Line Haemacytometer. Several types of Spencer microtomes will be set up for demonstration. Delineascopes for the projection of color slides, lantern slides, filmslides or opaque material will be exhibited. The new Quebec Colony Counter and a new Colorimeter will also be shown. Booths 263 and 264.

PHARMACEUTICALS AND BIOLOGICALS

ABBOTT LABORATORIES

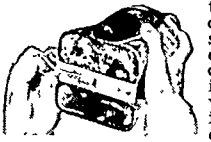
You will find a hearty welcome at the Abbott exhibit, Booths 234 and 235, where a [illegible] showing of their newer [illegible]ducts will be on display. [illegible] representatives will take pleasure in discussing new as well as old research items with you. A chat about your experiences with Abbott products (whether favorable or otherwise) will help all to keep 'abreast-of-the-times'.

AMERICAN RESEARCH PRODUCTS

An informative display featuring Vitamin D in the form of Viosterol (A.R.P.I. Process) in Oil, for the pharmaceutical trade, and Vitamin D in evaporated milk, for the fluid milk dealers, will await physicians visiting Booth 131. The story of what the product Embo (Wheat Embryo) can accomplish in cases of Vitamin B deficiency also will be told. Nationally known products of the parent company, General Mills, Inc., will be an interesting part of the exhibit.

ARLINGTON CHEMICAL COMPANY

Featured in Booth 118 will be the Arlington pollen extracts for diagnosis and treatment of hay fever, which are offered this year at a considerable reduction in price. Also a handy diagnostic protein outfit, consisting of eighty of the most common causative factors in allergic conditions, and a full line of food, epidermal and fungi proteins for diagnosis and desensitization. Dr. J. H. Frazer will be in charge.



ARMOUR LABORATORIES

Treatment of dyscrasias of the hematopoietic organs with particular reference to the erythrocyte and granulocyte series will be featured at the Armour exhibit, Booths 188 and 189. Graphs will show the increase in number of granulocytes and erythrocytes brought about by the administration of different preparations. The necessity for, and importance of careful and correct thyroid assay will be explained graphically.

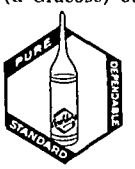
tions about and discuss the well-known Ciba specialties, among which are Digifoline, Dial, Lipoiodine, Nupercaine and Vioform. Your call will be welcomed.

CUTTER LABORATORIES

The complete line of Cutter biologicals and closely allied specialties, including their dextrose and other solutions in saftiflasks, will be exhibited. A new development is the ingenious hanging device now being built into the bottom of each saftiflask. It is completely out of the way until needed. In use, forms a sturdy hanger. Booth 226.

DAVIES, ROSE & COMPANY, LTD.

This year, as in the past, visitors will find the exhibit of Davies, Rose both interesting and informative. In Booth 23 Messrs. R. J. Mansfield, William F. Krause, and A. R. Gorham will be in attendance to explain in detail to callers the outstanding qualities of this firm's laboratory productions.



DRUG PRODUCTS CO. INC.

Visit Booth 157 where Hyposols and Pulvoids will be on display. Pulvoids Digitalis Folium, a mode of digitalis [illegible] standardized by the [illegible], Pulvoids Sulf- Sodium Cacodylate, all accepted by the Council on

a showing of the following "Council-Accepted" International Vitamin products: Halibut Liver Oil Plain in Liquid and Capsule form; Halibut Liver Oil with Vitamin D Concentrate in Liquid and Capsule form; Cod Liver Oil Concentrate in Liquid and Capsules; Cod Liver Oil Vitamin Concentrate in Tablets; and Viosterol (A. R. P. I. Process) in Oil.

LAKESIDE LABORATORIES, INC.

Their Council-Accepted Ampoule preparations, particularly ampoules of Dextrose (d Glucose) 50%, Sodium Cacodylate, Mercury Succinimide, Ephedrine Sulfate, Ephedrine Sulfate capsules for oral use, and Ephedrine Hydrochloride 3% for topical use, will be exhibited by Lakeside Laboratories in Booth 73. Members of the research staff will be in attendance.

LEDERLE LABORATORIES, INC.

The Lederle exhibit in Booths 201 and 202 will feature, in animated chart and diagram form, latest therapy on pernicious anemia, pneumonia and scarlet fever. Other new and interesting Lederle drugs and biologicals will also be shown.

ELI LILLY AND COMPANY

Eli Lilly, who pioneered the large-scale manufacture of insulin for the treatment of diabetes and of liver extract for the treatment of pernicious anemia, will dis-

Urginin ar[illegible] be featured [illegible] of Urginin a[illegible] fibrillation, [illegible] myocardial [illegible] vascular-renal disorders; and of Trichlorethylene in tic douloureux and painful conditions about the face and in certain types of cardiac pain, will be discussed. Other Council-Accepted specialties will also be on exhibit.

CHAPPEL LABORATORIES

An invitation is extended to all members of the medical profession to visit the technical exhibit of Council-Accepted, anti-anemia preparations made by Chappel. The development of Chappel pharmaceuticals has progressed as a result of scientific and clinical research, and representatives will attempt to demonstrate some of the aspects of these investigations in their Booth, No. 93.

CHURCH & DWIGHT CO., INC.

As makers of those two dependable old products, Arm and Hammer and Cow Brand Baking Soda since 1846, Church and Dwight are happy to invite you to visit their exhibit in Booth 76. Here attendants will be glad to discuss with you the many uses of Bicarbonate of Soda in medicine and tell you how quantity production and wide distribution have made this product available at low cost.

CIBA PHARMACEUTICAL PROD., INC.

Physicians are cordially invited to visit the Ciba Booth, No. 205, where the Assistant Medical Director and representatives of the firm will be glad to answer ques-

Pharmacy and Chemistry, will be presented. In addition, the advantages of the Pulvoids method of manufacture as compared to mass made tablets will be shown.

E. FOUGERA & COMPANY, INC.

How Lipiodol (Lafay), the original iodized oil, not only meets all the requirements for a nontoxic, nonirritating, radiopaque contrast medium for visualization of body cavities and tissue spaces, but presents unique advantages for this purpose, will be shown and discussed at the Fougera exhibit in Booth 145.

HOSPITAL LIQUIDS, INC.

Intravenous Solutions in Filtrair Dispensers will be exhibited at the Hospital Liquids display; Booth 169. Physicians will find interesting the manner in which solutions are kept pyrogen-protected and how they can be depended upon for sterility, security and safety in administration. Competent representatives will be on hand to discuss problems of parenteral therapy.

HYNSON, WESTCOTT & DUNNING

An exhibit featuring Mercurochrome and various pharmaceutical specialties of H. W. & D. manufacture will be found in Booth 177. There will also be a display of diagnostic apparatus and ampule solutions which have been developed in the firm's laboratories in cooperation with physicians. Competent representatives will be in attendance to demonstrate the products and to answer questions.

INTERNATIONAL VITAMIN CORP.

Complete information on all matters pertaining to vitamins will be available for physicians at Booth 267. Included will be

play these products in their exhibit, Booths 212, 213 and 214. Important drugs such as Sodium Amytal, Ephedrine, Carbarsone, and a representative list of biologicals will be included. Also an interesting laboratory demonstration of the physiological effects of the female sex hormones Estrone and Estriol will be presented.

MALLINCKRODT CHEMICAL WORKS

Physicans, their wives, and friends are invited to visit the Mallinckrodt Chemical exhibit, Space 170, where representatives will be glad to be of service in discussing any of the Mallinckrodt medicinal chemicals and specialties, such as ether, barium sulfate, Iodeikon, Isoiodeikon, Hippuran, the arsenicals, mandelates, sulfanilamide and soda lime.

MALTINE COMPANY

The various steps in the manufacture of Maltine with Cod Liver Oil, the result of more than six decades of continuous research and experience, will be shown in the Maltine exhibit, Booth 10. There will be shown illuminated slides, including photomicrographs indicating the minuteness and uniformity of the oil globules after the oil has been incorporated by vacuum process.

MC KESSON & ROBBINS, INC.

McKesson drug products approved by the A. M. A. will be featured in Space 110, together with an educational exhibit in pictures of the work carried on at the company's research laboratories and manufacturing plant at Bridgeport, Conn. Dr. A. L. Omohundro, director of laboratory research, will be in charge of the company's exhibit and will be assisted by the members of the laboratory staff.

MC NEIL LABORATORIES

In Booth 291 representatives of McNeil Labs. will exhibit and discuss such important contributions as Digitalis Duo-Test, which is assayed by both the frog and guinea-pig method; Rosebud Vaginal Tampons, the soft, cup-shaped tampons which help to prolong vaginal medication; Lubricant "McNeil," a velvety smooth jelly for digital and instrumental examination; Emulsion Castor Oil, a palatable, stable emulsion containing 50% (by volume) medicinally pure castor oil.

MERCK & COMPANY INC.

The Merck exhibit will feature such outstanding discoveries of the past few years as Thiamin Chloride and Nicotinic Acid. In the center panel of the display will be a striking enlarged illuminated photograph of the crystals of vitamin B_1 hydrochloride. Below, the intricacies of the vitamin B complex will be graphically illustrated. Nicotinic Acid and Thiamin Chloride will occupy large panels left and right of the center. Booths 271 and 272.

WM. S. MERRELL COMPANY

An interesting series of dioramas will show methods of procuring raw materials for use in Merrell pharmaceutical products. Diothane Hydrochloride, Fibrogen, and other Merrell therapeutic agents will be on display, and representatives will explain their action and use. Booth 22.

Salysal, "Rare Chemicals," the salicylic ester of salicylic acid designed to provide improved salicylate therapy by reducing local gastric irritation to a minimum; and Optochin Hydrochloride, ethylhydrocupreine, for pneumococcal infections of the eye.

RIEDEL-DE HAEN, INC.

At Booth 24 the Riedel-de Haen exhibit will feature Decholin and Decholin Sodium for the treatment of hepatic and biliary tract disorders. It will also present the scientific background of deoxycholic acid, the fat-digestant component of bile used to promote absorption of vitamin K.

SANDOZ CHEMICAL WORKS, INC.

Among the Council-Accepted pharmaceuticals of Sandoz in Booths 195 and 196, special attention will be given to Gynergen (ergotamine tartrate) extensively employed for the dramatic relief of migraine as well as for dependable uterine hemostasis; the gluconate preparation of calcium (Calglucon) whose advantages for oral, intramuscular and intravenous calcium therapy were first discovered in the Sandoz Research Laboratories; Scillaren and Scillaren-B, dependable cardiodiuretics; and Sandoptal, an efficient hypnotic.

G. D. SEARLE & COMPANY

A shadowgraph demonstration of various heart conditions will be on exhibition at the Searle Booth, No. 187. This ingenious device, developed by Dr. George Levene of Boston, enables the physician to view in

samples also available on tincture, capsules and tablets Digitalis Upsher Smith of U.S.P. XI potency. A cordial welcome to all visiting physicians.

E. R. SQUIBB & SONS

A new display featuring recent additions to the Squibb line of Council-Accepted nd pharmaceutical ound at Booths 85, ttendants, including he Squibb laboratthus affording an opportunity for personal discussion of special problems involving the use of the most recent therapeutic developments.

FREDERICK STEARNS & COMPANY

Doctors are cordially invited to visit the attractive Stearns Booth, No. 176, to view and discuss outstanding contributions to medical science developed in the firm's Scientific Laboratories. Representatives will be pleased to supply information on such outstanding products as Neo-Synephrin Hydrochloride. Information on Appella Apple Powder-Stearns for use in infantile diarrheas and dysenteries will be readily available.

WHITE LABORATORIES

Representatives of White Labs., Booth 210, will concentrate on furnishing practical information, backed by tests of time, as well as animal and clinical experience. These representatives will present Council-Accepted White's Cod Liver Oil Concentrate (liquid, tablets and capsules), together with pertinent information.

PARKE, DAVIS & COMPANY

Members of the staff of Parke, Davis will be at your service to tell you about some of [illegible] numerous scientific [illegible] Mapharsen, Adrenalin, [illegible] Theelin, Theelol, and biological products will be a part of this attractive exhibit. Booths 79, 80 and 81.

E. L. PATCH COMPANY

While many vitamin products have come and gone during recent years, there has recently been a decided trend back to Cod Liver Oil as a source of natural vitamins A and D. Patch's Cod Liver Oil will be featured at the Patch Company exhibit, Space 77. Patch representatives will be on hand to greet their friends in the medical profession and discuss the advantages of Cod Liver Oil as a source of the natural vitamins A and D.

PETROLAGAR LABORATORIES, INC.

At an interesting Petrolagar exhibit, Booth 121, representatives will be pleased to discuss the various uses of the product for the treatment of constipation. When you stop in to chat with one of the Petrolagar representatives, ask him to show you the new list of scientific motion pictures. There are numerous subjects especially suitable for classroom or lecture purposes.

PURITAN COMPRESSED GAS CORP.

The "Puritan Maid" brand of nitrous oxid, ethylene, oxygen, carbon dioxid, and carbon dioxid-oxygen mixtures, will be included in the exhibit of Puritan Compressed Gas Corp., Booth 108. Mr. George J. Hooper will be in charge of the exhibit and other authorized representatives will be in attendance.

RARE CHEMICALS, INC.

At Booth 161 Rare Chemicals will feature Gitalin (Amorphous), a rapid, dependable, glucosidal fraction of digitalis purpurea;

motion many of the typical pathologic alterations in cardiac contour and rhythm. A number of Searle representatives will be present and you are cordially invited to discuss with them various preparations.

SHARP & DOHME, INC.

Their complete line of Propadrine Hydrochloride products will be featured this year by Sharp & Dohme. In addition, there will be on display other items of interest in both the [illegible] and biological field. All [illegible] this Convention are [illegible] visit at Booths 193 and 191. Competent, well-informed representatives will be on hand to furnish information.

SMITH-DORSEY COMPANY

Physicians are cordially invited to visit the Smith-Dorsey Booth, No. 295, where they will find on display a number of products which meet the requirements of the Council on Pharmacy and Chemistry. Representatives in charge of the exhibit will be glad to furnish full information about products shown.

SMITH, KLINE & FRENCH LABS.

Physicians are invited to stop at Booth 155 to obtain complimentary samples of Benzedrine Inhaler. Representatives will be glad to answer questions about Benzedrine Sulfate Tablets, Benzedrine Solution and Pentnucleotide. Physicians may help themselves from convenient literature dispensers without the bother of leaving their names. They will not be solicited to register.

UPSHER SMITH COMPANY

Booth 158, Aisle G, between registration tables and main entrance, will feature Pyrethrum Ointment, Council-Accepted non-irritating scabies treatment, which has a pleasant odor and is clean and easy for your patients to use. Information and

WINTHROP CHEMICAL CO., INC.

[illegible] is extended by Booth 95, where ly discuss the latest preparations made available by this firm. You will receive valuable booklets dealing with anesthetics, analgesics, antirachitics, antispasmodics, antisyphilitics, diagnostics, diuretics, hypnotics, sedatives and vasodilators.

JOHN WYETH & BROTHER, INC.

In Booth 230, Dean Cornwell's heroic canvas, "Beaumont and St. Martin" will be exhibited by John Wyeth & Brother. This is the first showing of this painting at an American Medical Association Convention and is the first painting in a series to be presented by Wyeths. The series is entitled "Pioneers in American Medicine," and will dramatize the contributions of Americans to the advancement of medicine. Arrangements for reproductions of the painting may be made at the booth.

PHYSICAL THERAPY AND X-RAY

ADLANCO X-RAY CORPORATION

In Booth 27 the Adlanco X-Ray exhibit will feature the Siemens Planigraph, which permits fluoroscopy and radiography of any predetermined layer within the patient's body without anterior and posterior obstructions. The "Original Ultratherm" ultra short wave apparatus, as well as the smallest shock-and-ray-proof x-ray unit "Heliosphere," will also be exhibited. A call to inspect these new and important contributions will be well worth while.

(Continued on advertising page 84)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Society News.—Dr. Sumner L. S. Koch, Chicago, discussed "Surgical Management of Fractures, Lacerations and Infections of the Hand" before the Los Angeles Surgical Society March 24. —— Among others, Dr. Wilbur Bailey addressed the Trudeau Society in Los Angeles March 28 on "Spontaneous Pneumothorax of Nontuberculous Origin."

Changes in Health Officers.—The *Weekly Bulletin* of the California Department of Public Health recently announced the following changes in health officers:

Dr. Albert B. Gray, Dorris, succeeding Dr. Paul F. Dieffenbacher.
Dr. David G. Schmidt, Larkspur, succeeding Dr. Cornwall C. Everman.
Dr. James D. Coulter, Portola, of Plumas County.
Dr. *Harry M. Grayman of Dos Palos to succeed Dr. Edwin A.* Patterson.
Dr. James L. Faulkner, Red Bluff, of Tehama County, succeeding Dr. Otho T. Wood.
Dr. William E. Fountain, Merced, of Merced County, succeeding Dr. Clarence C. Fitzgibbon.

Dr. Reuben L. Kaufman, who has served for many years as district health officer at Whittier, under the Los Angeles County Health Department, has been appointed health officer of Riverside County to succeed the late Dr. Wendall A. Jones.

COLORADO

Society News.—At a special meeting Dec. 28, 1938, the Colorado Hospital Association adopted new by-laws to make the structure of the state association conform more closely to those of the American Hospital Association.

Personal.—Dr. Thaddeus M. Koppa, Cheyenne, Wyo., has been appointed in charge of the Otero County health unit, pending the return of Dr. Lynn J. Lull, Branford, Conn., who is taking a year's graduate study at Yale University.

DELAWARE

Society News.—The Delaware Academy of Medicine, Wilmington, was addressed March 3 by Dr. Robert B. Osgood, Boston, on "The Ethics of Medicine."——Dr. Amos R. Koontz, Baltimore, addressed the New Castle County Medical Society, Wilmington, recently on "The Use of Fascia in Surgery."

Delaware Society to Observe Sesquicentennial.—Plans are under way to observe in October the sesquicentennial of the Medical Society of Delaware. The organization was incorporated by a special act of the legislature Feb. 3, 1789, thus making it the third oldest medical society and the second oldest medical corporation in the United States, according to the state medical journal. New Jersey holds first place in both categories, with Massachusetts in second place as a society. The *celebration will be held in Wilmington.*

ILLINOIS

Personal.—Dr. Louis J. Frederick has been appointed health commissioner of Joliet, succeeding the late Dr. Edward J. Higgins.

Chicago

Necropsy Rate in Research Hospital.—A delayed report from the Research and Educational Hospital of the University of Illinois, Chicago, indicates that this institution has a record of 83.2 per cent necropsies for the year 1938. Other approved internship hospitals having over 70 per cent necropsies were reported on page 924 of the Hospital Number of THE JOURNAL March 11.

Public Session on the Hard of Hearing.—The Chicago Medical Society will hold a public meeting on "What Chicago Does for Its Hard of Hearing" at the Chicago Woman's Club April 19. The principal speakers will include Frank L. Beals, assistant superintendent, Chicago schools; Dr. Robert Black, acting president, board of health; Dr. Walter H. Theobald, secretary, Chicago Laryngological and Otological Society; Dr. Samuel Salinger, clinical professor of otorhinolaryngology, Loyola University School of Medicine; Miss Irene Hubbell, president, and Dr. Austin A. Hayden, chairman, board of directors of the Chicago League for the Hard of Hearing, and Edward J. Kelly, mayor.

Society News.—Among others, Drs. Arthur K. Koff and Edith L. Potter addressed the Chicago Gynecological Society March 17 on "Dangers of Excessive Development of Human Fetus." —— The Chicago Society of Allergy was addressed March 20 by Dr. Israel Davidsohn on "Heterophilic Phenomena in Immunology."——Dr. Isadore Pilot addressed the Chicago Club for the Study of Rheumatic Diseases March 22 on "Different Features of Bacterial and Rheumatic Arthritis," and Drs. Catharine E. Logan and Eugene F. Traut, Oak Park, Ill., "Clinical and Bacteriologic Improvement in Chronic Arthritis Following the Use of Sulfanilamide." —— A symposium on commitment to mental hospitals was presented before the Illinois Psychiatric Society March 2 by Drs. Francis J. Gerty, Thomas M. French and Abraham A. Low.

INDIANA

Director of Research on Sickness Insurance.—Dr. Walter U. Kennedy, Newcastle, has been appointed director of research on sickness insurance of the Indiana State Medical Association. The position is a new one. Dr. Kennedy graduated at Barnes Medical College, St. Louis, in 1898.

Marriage Law Now in Effect.—A law has been enacted in Indiana governing applicants for licenses to marry. Applicants must submit to tests for venereal diseases. Application for a license must be made in the home county of the bride or in the home county of the bridegroom if the bride does not reside in Indiana; if neither is a resident of the state a license will be refused. Notice of intention to marry must be publicly certified five days before the ceremony.

Semiannual District Meeting at Peru.—The sixty-first semiannual meeting of the Eleventh Indiana Councilor District Medical Association will be held at Peru May 10. A clinic on renal diseases, conducted by Dr. Howard M. Odel, Rochester, Minn., will open the session. The speakers in the afternoon will include Drs. Herbert M. Rhorer, Kokomo, who will give the presidential address; Ernest O. Asher, New Augusta (subject not announced); Ora G. Brubaker, North Manchester, "The Acute Ear," and Dr. Odel, "Essential Hypertension—Diagnosis and Management." Andrew W. Cordier, Ph.D., Manchester College, North Manchester, will give an address at the banquet, under the auspices of the Miami County Medical Society, on "Germany and Her Neighbors."

KANSAS

The Wichita Medical Supplement.—The Wichita *Sunday Beacon* dedicated an eight page section March 19 to the "men of medicine of Wichita." Carrying a caption "A Dedication and Tribute to the 'Regular' Family Doctor," the first page shows a reprint of the painting "The Doctor" by Fildes. Articles describe the activities of the Sedgwick County Medical Society and its auxiliary. There are also discussions of diseases and of hygiene. The *Eagle* and the *Beacon*, in separate supplements, have thus honored the local profession for the past five years.

MAINE

Society News. — The Cumberland County Medical Association was addressed in Portland recently by Dr. Roger I. Lee, Boston, among others, on "The Doctor's Dilemma, When and If the Government Goes Into the Practice of Medicine in a Big Way."——At a meeting of the Portland Medical Club recently Dr. Edward A. Greco discussed "The Heart in Lung Diseases."——The Kennebec County Medical Association held a clinical session in Waterville February 16; the speakers included Drs. Edward H. Risley on "Ruptured Gallbladder and Incarcerated Inguinal Hernia" and Edwin R. Irgens, "Plastic Operation for Deformity of Face Secondary to Operation for Carcinoma of Antrum."——Dr. Everett D. Kiefer, Boston, discussed "Management of Ulcerative Colitis and Functional Colonic Disorders" before the Knox County Medical Society in Rockland February 14.——Dr. Siegfried J. Thannhauser, Boston, addressed the Oxford and Penobscot county medical societies in Rumford and Bangor respectively on diseases of the liver.——Dr. Adam P. Leighton, Portland, addressed the Maine Pharmaceutical Association recently in Augusta on "The Relationship of the Doctor to the Druggist."

MARYLAND

Buildings for Tuberculous Patients.—Buildings to house 200 additional patients are under construction from funds provided by the state legislature, according to the Baltimore *Health News.* These beds are expected to be ready for occupancy October 1. A request is to be made of the legislature

by the board of managers of the state tuberculosis sanatorium commission for funds for an additional hundred beds at Henryton, a sanatorium for Negroes, and for funds to establish a branch hospital for Negro patients on the Eastern shore. It is also hoped to have a building in operation October 1 for the sole purpose of surgical treatment of tuberculosis of the lungs.

Annual Meeting of Medical and Chirurgical Faculty.—Dr. Victor F. Cullen, acting president, will open the annual meeting of the Medical and Chirurgical Faculty of Maryland in Baltimore April 25 with an address on "Tuberculosis of the Past and Present." Trimble lectures will be given by Drs. John Alexander, Ann Arbor, Mich., and Haven Emerson, New York, on "Management of Bronchiectasis and Abscess of the Lung" and "Administrative Medicine" respectively. Dr. Wiley D. Forbus, Durham, N. C., will deliver the first Stokes lecture on "Variations in Morphological Reaction to Injury." There will be a symposium on appendicitis by Drs. Victor D. Miller and Arthur M. Shipley, and a round table luncheon with the following speakers:

Dr. Thomas B. Aycock, Surgery of the Chest.
Dr. Bartus T. Baggott, Early Diagnosis of Tuberculosis.
Dr. Thomas R. Chambers, Rectal Surgery.
Dr. Richard G. Coblentz, Cerebral Trauma.
Dr. John A. Campbell Colston, Urology.
Dr. Ira A. Darling, Sykeville, The Responsibility of a State Mental Hospital to the Community.
Dr. Nicholson J. Eastman, Obstetric Hemorrhage.
Dr. John S. Fenby, Common Problems in Pediatrics.
Dr. Whitmer B. Firor, Radiation Therapy of Inflammatory Conditions.
Dr. Francis J. Geraghty, The Treatment of Pneumonia with Sulfapyridine.
Dr. Charles Loring Joslin, The Treatment of Pneumonia in Infants and Children with Sulfapyridine.
Dr. John Mason Hundley Jr., Malignancy of the Female Generative Tract.
Dr. Raymond Hussey, Relationship of Heart Disease to Pulmonary Disease.
Dr. Edward A. Looper, Remarks on Diseases of the Accessory Sinuses.
Dr. Llewellyn Williams Lord, Eczema.
Dr. Joseph E. Moore, Legislation Regarding Syphilis.
Dr. Moses Paulson, Practical Aspects of the Diarrheas and Dysenteries of the Adult.
Dr. Floyd Elmer Shaffer, Sparrows Point, Accident Surgery.
Dr. Richard W. TeLinde, Office Gynecology.
Dr. Allen F. Voshell, Problem Fractures.
Dr. Frank B. Walsh, Ophthalmology.

MASSACHUSETTS

George Bigelow Memorial.—The Boston Medical Library has received $1,038.30 to provide a permanent fund, the income of which will be used to purchase books on public health, cancer, medical economics and related subjects to serve as a memorial to the late Dr. George H. Bigelow. A section in Holmes Hall has been set apart for these books. The books are to be selected by a committee composed of the librarian of the Boston Medical Library, the dean of the Harvard School of Public Health and the commissioner of public health. As a nucleus for the collection, the Commonwealth Fund of New York has contributed fourteen volumes of its publications and a few writers on public health have donated copies of their books. It is hoped that additional gifts of books or money for the Bigelow Library will be made from time to time and sent to the librarian of the Boston Medical Library. According to the *New England Journal of Medicine*, two friends of Dr. Bigelow who prefer to be anonymous have presented to the library a bookplate, designed by Miss Mary Sears, to be placed in each book purchased by the fund. Each donor has received a print of the bookplate, which carries an excellent likeness of Dr. Bigelow. The fund was collected by a memorial committee, members of which were Drs. Henry D. Chadwick, Boston, chairman; Dr. Clarence L. Scamman, New York; Dr. Charles F. Wilinsky, Boston; Frank Kiernan, A.B., New York; Dr. Gaylord W. Anderson, Minneapolis; Dr. Walter P. Bowers, Clinton; Ida M. Cannon, R.N., and Curtis M. Hilliard, A.B., Boston; Dr. Benjamin Harrison Ragle, Boston; Dr. Wilson G. Smillie, New York, and Mr. Horace Morison.

MICHIGAN

Consultant on Maternal Health.—Dr. Alexander M. Campbell, Grand Rapids, has been appointed full time consultant to the bureau of maternal and child health of the state department of health. He will carry on a program jointly sponsored by the state medical society, the W. K. Kellogg Foundation, the University of Michigan and the state department of health, working with the maternal health committees of the county medical societies in the state, newspapers reported February 12.

New Maternity Service.—A new health service providing medical, nursing and hospital care for expectant mothers who otherwise would not be able to secure such care was to be started in Schoolcraft County March 15. Organized by the state department of health with social security funds, the service is under the immediate supervision of Dr. Ervin J. Brenner, director of the Alger-Schoolcraft Health Department in cooperation with the local physicians. Funds will be provided to pay physicians for complete obstetric service, including antepartum and postpartum care. Hospital care will be available when needed and the family physicians will be given nursing assistance for both home and hospital deliveries. Physicians wishing to use this service should submit their applications to Dr. Brenner's office in Manistique.

Meeting of Industrial Physicians.—The Michigan Society of Industrial Physicians and Surgeons will hold its annual meeting at the Hotel Olds, Lansing, April 19. The speakers will include:

L. J. Carey, LL.B., Detroit, general counsel, Michigan Mutual Liability Insurance Company, Medical Service for the Small Employer.
Dr. Gordon B. Myers, Detroit, professor of medicine, Wayne University College of Medicine, Sulfanilamide in Surgical Infections.
Dr. William L. Benedict, professor of ophthalmology, University of Minnesota Graduate School of Medicine, Rochester, Preventable Industrial Eye Accidents.
Dr. Frank T. McCormick, Detroit, Medical Relations in Industrial Surgery.

Warnings and precautions in management against disabling results from injuries will be given by the following: Drs. Alfred H. Whittaker, injuries to hips; Grover C. Penberthy, Detroit, elbows; Carl E. Badgley, Ann Arbor, backs; Max M. Peet, Ann Arbor, skulls.

NEVADA

Annual Registration Due May 1.—All persons holding licenses to practice medicine in Nevada are required by law to pay annually to the treasurer of the Board of Medical Examiners, on or before May 1, a tax of $2. Failure to do so operates to forfeit a licentiate's right to practice medicine and his license to practice can be reinstated thereafter only on the payment of a $10 penalty.

NEW MEXICO

Biennial Report of State Health Department.—The biennial report of the state department of public health for 1937 and 1938 indicates that the department has been enlarged by a division of health education, a school health consultant and a milk sanitarian. With funds provided by the Children's Bureau of the U. S. Department of Labor, a demonstration unit has been established in San Miguel County as a training field for public health nurses. Sixteen nurses have been added to the department's staff during the biennium, bringing the total number to seventy-four. Influenza was the most prevalent communicable disease in 1937 and measles in 1938; measles came second in 1937 and syphilis in 1938; 130 fewer cases of typhoid were reported in 1938 than the average for the five preceding years. Tuberculosis is one of New Mexico's major problems. In 1937 there were 1,392 cases reported of which 542 originated outside the state. The state's infant death rate, highest in the United States, is chiefly caused by diarrhea and enteritis. A dysentery research project, which has been in progress for several years, continues to operate. Through the U. S. Public Health Service the state has initiated a venereal disease control project in Bernalillo County. The engineering division in cooperation with the University of New Mexico made a survey of fluorine in public water supplies. Samples from 359 supplies were examined. Of 157 communities of considerable size, thirty-five were found to have water containing fluorine above the danger point of 0.9 parts per million. In the division of maternal and child health, established in 1936 under the provisions of the Social Security Act, the largest part of the funds have been used to increase the number of public health nurses working in rural areas. Maternity and child health clinics are conducted by physicians who are members of the state medical society. Since 1937, 900 of these clinics have been conducted, most of them by local physicians. A midwife consultant nurse has been added to the staff to instruct midwives, of whom there are about 800 in the state. The state laboratory has moved into a new building. In 1937 the laboratory examined 60,220 specimens and in addition performed 50,657 agglutination tests for Bang's disease in cooperation with the U. S. Bureau of Animal Industry. In 1938, 72,563 specimens were examined and 39,684 agglutination tests were performed. Tests for syphilis were made on 22,596 specimens in 1937 and 26,784 in 1938.

NEW YORK

Society News.—The New York State Association of Public Health Laboratories will hold its twenty-third annual meeting at Grasslands Hospital, Valhalla, May 8.——Dr. John E. Jennings, Brooklyn, addressed the Medical Society of the County of Nassau at Garden City March 28 on "Management of Carcinoma of the Colon."——Drs. Enrico C. Soldini, Staten Island, and Nathan Rosenthal, New York, addressed the Richmond County Medical Society in February at St. George on "Management of the Diabetic Patient" and "Diseases of the Blood" respectively.——Dr. Charles Gordon Heyd, New York, addressed the Medical Society of the County of Albany March 22 on "Diagnosis and Treatment of Cancer of the Colon and Rectum."

Alumni Clinical Day in Buffalo.—Alumni of the University of Buffalo School of Medicine will have their annual clinical day April 22 at the Hotel Statler, Buffalo. The speakers will be:

Dr. Elmore B. Tauber, professor of dermatology and syphilology, University of Cincinnati College of Medicine, Cincinnati.
Dr. Horton Casparis, professor of pediatrics, Vanderbilt University School of Medicine, Nashville, Tenn.
Dr. Edward H. Dennen, professor of gynecology and obstetrics, New York Polyclinic Medical School and Hospital, New York.
Dr. Harry E. Mock, associate professor of surgery, Northwestern University Medical School, Chicago.
Dr. Ernest Perry McCullagh, director of the department of endocrinology and metabolism, Cleveland Clinic, Cleveland.
David L. Thomson, Ph.D., professor of biochemistry, McGill University Faculty of Medicine, Montreal, Que.

The annual dinner will be held at the Statler.

New York City

Biggs Memorial Lecture.—Mr. Frederick Osborn, research associate in anthropology at the American Museum of Natural History, delivered the fourteenth Hermann Michael Biggs Lecture of the New York Academy of Medicine, April 6, on "Significance to Medicine of Present Population Trends."

Seventh Harvey Lecture.—Charles H. Danforth, Ph.D., professor of anatomy, Stanford University School of Medicine, San Francisco, will deliver the seventh Harvey Society Lecture of the current series at the New York Academy of Medicine April 20. Dr. Danforth will speak on "Genic and Hormonal Factors in Some Biological Processes."

Dinner to Eve Curie.—The New York City Cancer Committee of the American Society for the Control of Cancer will sponsor a dinner in honor of Mlle. Eve Curie, daughter of Pierre Curie and Madame Curie, discoverers of radium, Tuesday April 18. The dinner will be at the Cosmopolitan Club, 129 East Sixty-Fifth Street. Mlle. Curie is the author of the recent biography of her mother.

Friday Afternoon Lectures in Brooklyn.—The spring series of Friday afternoon lectures sponsored by the Medical Society of the County of Kings included the following lectures:

Dr. James Alexander Miller, Modern Approach to the Early Diagnosis of Pulmonary Tuberculosis, March 17.
Dr. Joseph E. Milgram, Subdeltoid Bursitis—Its Pathology, Differential Diagnosis and Office Treatment, March 24.
Dr. Theodore J. Curphey, New Contributions to Laboratory Medicine—Their Clinical Interpretations and Significance, March 31.
Dr. Harry M. Greenwald, Diagnostic and Therapeutic Aspects of Splenic Enlargement, April 14.

Large Chronic Disease Hospital Completed.—Construction has been completed at the new Hospital for Chronic Diseases on Welfare Island and the hospital will be opened about July 1, it was announced February 4, when a group of 1,500 physicians, nurses and social workers inspected the new institution. The hospital has four four-story ward buildings, with a seven story administration building in the center. The bed capacity of the hospital will be 1,600, and the building has cost almost $8,000,000. When it is opened 800 patients will be brought from other city institutions, thus relieving overcrowded buildings originally intended for acutely ill patients.

Society News.—A symposium on mental health problems was presented at a meeting of the Medical Society of the County of New York March 27 by Drs. Gerald R. Jameison, Severo Eugene Barrera, Karl M. Bowman and Lawrence S. Kubie.——The program of the Medical Society of the County of Kings March 21 included as speakers: Drs. Joseph Slavit, on "Socialized Medicine"; Kingsley Roberts, "Group Practice and Its Relationship to the Future of American Medicine"; Charles Gordon Heyd, "Medical Expense Indemnity Insurance," and Haven Emerson, "The National Health Program."——Drs. Burrill B. Crohn and Richard Lewisohn addressed the Bronx County Medical Society March 15 on medical and surgical aspects, respectively, of ulcer of the stomach and duodenum.——Dr. James A. Cahill Jr., Washington, D. C., addressed the Queensboro Surgical Society April 19 on "Trauma of the Abdomen and Chest."

Industrial Workers Tested for Tuberculosis.—The New York City Department of Health with the assistance of the Works Progress Administration is conducting tests among the 15,000 fur workers in New York to determine the prevalence of tuberculosis in this occupation. When the program among the fur workers is completed it is hoped that other occupational groups may be examined. Although this is the beginning of the tuberculosis service among industrial workers, the health department has examined more than 160,000 in its tuberculosis program among other groups, begun in December 1933. The tests have been given to 5,000 residents of or transients at the Municipal Lodging House, 14,000 high school children, 8,857 members of the National Youth Administration, 2,500 residents of West New Brighton, Staten Island, 4,000 men in the Rikers Island Penitentiary, 1,000 women in the Women's House of Detention, 1,000 Hunter College students, 1,000 students of the College of the City of New York and 600 of New York University. The percentage of infection among these groups runs from 0.5 per cent to 16 per cent. The highest percentage was found among the transients and homeless men of the Municipal Lodging House.

NORTH CAROLINA

Duke Celebrates Centennial.—Duke University announces a formal celebration of its centennial April 21-23. The entire scholastic year 1938-1939 was designated as a time for celebration of the century of development that has resulted in the Duke University of today. The university is built around Trinity College, which goes back to 1838-1839, when a group of Methodists and Quakers established a school they called Union Institute. The school kept this name until 1851, when it became a teachers' college and was called Normal College. Just before the Civil War the college was affiliated with the North Carolina Methodist Conference and named Trinity College, which continues today as the undergraduate college for men in the university. Duke was organized in 1924. In November 1938, the university presented a three day symposium on medical problems as part of the centennial observance (THE JOURNAL, Oct. 8, 1938, page 1389). At the coming ceremonies there will be discussions of "Southern Contributions to American Education," "Education and the Public" and "The University and the Nation."

OHIO

Personal.—Dr. Emily J. Widdecombe, Kent, for many years secretary of the Portage County Medical Society, was recently honored for her service. The society presented her a gold and amethyst bracelet.——Dr. Clyde W. Dawson, Columbus, has been appointed orthopedist in the medical section of the state industrial commission.——Dr. Edward S. Folk has recently been elected mayor of Canton.

Postgraduate Assembly at Youngstown.—The Mahoning County Medical Society will present its twelfth Annual Postgraduate Assembly in Youngstown April 20 with a group from the University of Pennsylvania School of Medicine, Philadelphia, as its guests. The following program is announced:

Dr. Charles C. Wolferth, Cardinal Features of Coronary Disease; Physical Examination of the Heart with Special Reference to Heart Sounds.
Dr. Eugene P. Pendergrass, Silicosis and Silicosis with Infection; Roentgen Therapy of Infections.
Dr. Richard A. Kern, General Principles of Allergy and Clinical Manifestations of Allergy (Part 1); Clinical Manifestations of Allergy and Principles of Diagnosis and Treatment (Part 2).
Dr. Joseph Stokes Jr., Recent Advances in the Study and Treatment of Certain Virus Diseases; Prophylaxis and Treatment in Certain Acute Infectious Diseases.

PENNSYLVANIA

Society News.—Dr. William Devitt, Allenwood, was elected president of the Pennsylvania Tuberculosis Society for the fifth time at its annual meeting in Pittsburgh February 14-15. Dr. Charles Howard Marcy, Pittsburgh, was elected secretary.

Philadelphia

Joint Obstetric Meeting.—The Obstetrical Society of Philadelphia entertained the New York Obstetrical Society, Obstetrical Society of Boston, the Pittsburgh Obstetrical and Gynecological Society and the Washington Gynecological Society April 6. Clinics were held in various hospitals during

the day and the Philadelphia group gave a dinner in the evening at the University Club, at which Dr. Benjamin P. Watson, New York, presided.

Society News.—Speakers at a meeting of the Philadelphia Urological Society March 27 were Drs. Charles H. de T. Shivers and Kenneth P. Henderson, Atlantic City, N. J., on "Tumors of the Bladder; A Review of 101 Cases" and Clarence R. O'Crowley, Newark, N. J., "Polycystic Kidneys."——Dr. Howard H. Bradshaw, among others, addressed the Laennec Society of Philadelphia, March 28, on "Neurogenic Tumors of the Thorax."——Dr. John F. Fulton, Sterling professor of physiology, Yale University School of Medicine, New Haven, addressed the Jefferson Neurological Society, March 22, at Jefferson Medical College, on "Hypothalamus and Regulation of Autonomic Function."

SOUTH DAKOTA

State Medical Meeting at Aberdeen.—The fifty-eighth annual session of the South Dakota State Medical Association will be held in Aberdeen April 24-26 under the presidency of Dr. John F. D. Cook, Pierre. The following guest speakers are on the program:

Dr. Edward D. Allen, Chicago, Diagnosis and Treatment of Leukorrhea; Diagnosis and Treatment of Endometriosis.
Dr. Don C. Sutton, Chicago, Arteriosclerosis—Etiology, Symptoms and Treatment.
Dr. Hewitt B. Hannah, Minneapolis, An Analysis of Factors in Personality Influencing Health.
Dr. Henry W. Meyerding, Rochester, Minn., Backache.
Dr. Henry L. Williams Jr., Rochester, Minn., Physiologic Phenomena Which Are Misinterpreted as Nasal Disease.
Dr. Joseph C. Ohlmacher, Vermillion, Practical Cooperation Between the Practicing Physician and the Diagnostic Laboratory.
Dr. Clifford J. Barborka, Chicago, Recent Advances in Nutrition.
Dr. Edwin M. Miller, Chicago, Bowel Obstruction in the Newborn.
Dr. Harry Culver, Chicago, Epithelial Tumors of the Bladder.
Dr. Fay H. Squire, Chicago, Diagnosis and X-Ray Picture of Peptic Ulcer During Medical Management.
Dr. Gerald J. Van Heuvelen, Pierre, Venereal Disease Control.

There will be clinics by Drs. Meyerding, Sutton, Culver, Barborka, Squire and Miller. The South Dakota Academy of Ophthalmology and Otolaryngology will hold its meeting Tuesday April 25 with the following speakers: Drs. Henry L. Williams Jr., Rochester, Minn., "Effect of Radium in Maintaining Patency in the Nasofrontal Duct" and "External Operations on the Frontal Sinus"; Walter H. Fink, Minneapolis, "Routine Ocular Muscular Investigation"; Henry P. Rosenberger, Bismarck, N. D., "Suppurations in the Neck," and Edward A. Rudolph, Aberdeen, "Perforating Injuries of the Eye."

TENNESSEE

Personal.—Dr. Fray O. Pearson, Livingston, has been appointed health officer of Hamilton County to succeed Dr. Jesse C. Eldridge, Chattanooga, resigned.——Dr. J. W. Erwin, Blountville, has been appointed health officer of Sullivan County to succeed Dr. Fred L. Moore, Blountville, who resigned to join the faculty of Long Island College of Medicine, New York.

New Graduate Courses at Vanderbilt.—A new series of graduate courses at Vanderbilt University School of Medicine, Nashville, is to be made available to physicians under the auspices of the Commonwealth Fund of New York, according to the *Journal of the Tennessee State Medical Association.* Four courses of one month's duration will be given, medicine and surgery from June 15 through July 17 and pediatrics and obstetrics from July 17 through August 17.

Society News.—Dr. James B. Neil, Knoxville, addressed the Knox County Medical Society, Knoxville, March 7 on prostatic resection.——Dr. Douglas Chamberlain, Chattanooga, addressed the Chattanooga and Hamilton County Medical Society March 23 on "Ménière's Disease" and Dr. Gene H. Kistler, Chattanooga, March 16 on "Pruritus Ani."——Drs. Duane M. Carr and James S. Speed, Memphis, addressed the Madison County Medical Society, Jackson, March 7 on treatment of pulmonary tuberculosis and causes of low back pain respectively.

TEXAS

Hospital News.—Dr. Michael A. Cunningham, medical director of the Holy Cross Sanatorium, Holy Cross, N. M., has been appointed superintendent and medical director of the Jefferson County Tuberculosis Hospital, Beaumont. Mrs. Caroline Van Zandt, who has been superintendent for several years, will remain at the hospital in an administrative capacity.

District Meeting.—Guest speakers at a meeting of the Northwest Texas District Society at Mineral Wells, February 14, were Drs. Willis C. Campbell, Memphis, Tenn., on "Surgery of the Hip"; Tinsley R. Harrison, Nashville, Tenn., "The Value of Drugs in the Management of Cardiac Disease"; Stanley George Wolfe, Shreveport, La., "Diagnosis and Treatment of Undulant Fever"; Edward H. Schwab, Galveston, "Diagnosis of Coronary Occlusion," and Homer Prince, Houston, "Practical Points in Treating Infected Allergic Patients."

Society News.—At a meeting of the Dallas County Medical Society March 9 the speakers were Drs. Charles L. Martin on "Treatment of Sterility by Fallopian Tube Inflation with X-Ray Control"; John E. Ashby, "Drugs in the Treatment of Congenital Syphilis," and Tate Miller, "Colitis."——Drs. Louis F. Hamilton and Ira L. Howell addressed the El Paso County Medical Society, El Paso, February 13 on "Uterine Fibroids" and "Amnesia" respectively.——Drs. Neil D. Buie and Howard O. Smith, Marlin, addressed the Falls County Medical Society, Marlin, January 9 on "Bright's Disease" and "Cancer of the Breast" respectively.——Dr. Louis F. Knoepp, Beaumont, addressed the Jefferson County Medical Society, Beaumont, January 9 on "Presacral Neurectomy."

UTAH

Society News.—Dr. Orin A. Ogilvie, Salt Lake City, recently addressed the Weber County Medical Society on the diagnosis, prognosis and treatment of malignant tumors of the skin.

Personal.—Dr. George N. Curtis, Salt Lake City, has been appointed medical director and superintendent of the Salt Lake County General Hospital, Salt Lake City, to succeed Dr. Robert J. Alexander, according to *Modern Hospital.*

VIRGINIA

Professor Retires.—Dr. Halstead S. Hedges has resigned as professor of diseases of the eye at the University of Virginia Department of Medicine, Charlottesville, after thirty-four years in that position. Dr. Hedges graduated from the university medical department in 1889 and took his medical degree there in 1892. After several periods of study in New York he was appointed professor in 1905.

Regional Meeting.—A symposium on diseases of the chest was presented at a meeting of the Southside Virginia Medical Association in Franklin March 21. The speakers were Drs. John A. Proffitt, Burkeville, "Early Signs and Symptoms of Tuberculosis of the Chest"; Porter P. Vinson, Richmond, "Aids in the Early Diagnosis of Primary Carcinoma of the Bronchus"; Wright Clarkson, Petersburg, "The X-Ray in the Diagnosis of Diseases of the Chest"; Louis H. Clerf, Philadelphia, "Bronchiectasis: A Consideration of Its Causes and Its Prevention" and Isaac A. Bigger, Richmond, "Surgery of the Chest."

Society News.——Dr. Priscilla White, Boston, addressed the Richmond Academy of Medicine March 7 on "Some of the Newer and Interesting Phases of Diabetes."——Dr. Edwin E. Barksdale, Danville, addressed the Patrick Henry Medical Society in Martinsville January 13 on cutaneous diseases of importance to the general practitioner.——At a meeting of the Roanoke Academy of Medicine January 9 the speakers were Drs. Charles W. Dorsey on "Obstetrical Analgesia, Amnesia and Anesthesia"; Charles H. Peterson, "Use of the Roentgen Ray in Diagnosis and Treatment of Mediastinal Diseases," and Roger H. Du Bose, modification of fresh cow's milk with use of honey.

WISCONSIN

Personal.—The village of Cashton and the surrounding community honored Dr. Cornelius H. Cremer with a reception February 17 celebrating his fiftieth anniversary in the practice of medicine. Dr. Cremer, 74 years old, is president of the state board of medical examiners. About 1,200 persons attended the celebration.

Society News.—Dr. Robert F. McNattin, Chicago, addressed the Brown-Kewaunee-Door County Medical Society, Green Bay, March 9 on "Treatment of Benign and Malignant Lesions by Radiation Therapy."——Dr. Albert W. Bryan, Madison, Wis., discussed "Management of Neurosis" before the Barron-Washburn-Sawyer-Burnett County Medical Society, Barron, March 7.——Dr. Horton C. Hinshaw, Rochester, Minn., addressed the La Crosse County Medical Society, La Crosse, March 14 on "Recent Advances in Treatment of Pneumonia."——Dr. Ovid O. Meyer, Madison, addressed the

Outagamie County Medical Society, Appleton, March 16 on "Diagnostic Considerations in Diseases of the Spleen" and Dr. Victor F. Marshall, Appleton, on "Some Indications for Splenectomy."——Dr. Walter A. Fansler, Minneapolis, addressed the Pierce-St. Croix County Medical Society, New Richmond, March 16 on "Treatment of Hemorrhoids and Anal Fissure." ——Drs. Benjamin B. Souster and Gordon R. Kamman, St. Paul, addressed the Polk County Medical Society, Amery, March 16 on "The Mechanism of the Heart Beat and Electrocardiography" and "Psychiatric Disorders Occurring in Middle Life" respectively.

Lectures and Clinics for Practitioners.—Lectures and clinics for practicing physicians will be held in Appleton April 18, in Madison April 19 and in Eau Claire April 20, a new activity under the auspices of the council on scientific work of the State Medical Society of Wisconsin. The speakers will be:

Dr. Alexis F. Hartmann, St. Louis, Immunologic Program in Family Practice.
Dr. Cleveland J. White, Chicago, Office Management of Syphilis.
Dr. Richard W. TeLinde, Baltimore, Office Gynecology; Practical Aspects of Gynecologic Endocrinology.
Dr. Francis D. Murphy, Milwaukee, Treatment of Acute Medical Emergencies.
Dr. Carl W. Eberbach, Milwaukee, The Acute Abdomen.
Dr. Leland S. McKittrick, Boston, Early Recognition and Early Eradication of Cancer.
Dr. Marion A. Blankenhorn, Cincinnati, Deficiency Diseases as Seen in Office Practice and Vitamin Therapy.

GENERAL

St. Louis University Alumni Dinner.—The alumni of St. Louis University School of Medicine will hold a reunion dinner at the Missouri Athletic Association, St. Louis, May 17, 6:30 p. m. Additional information may be obtained from the alumni office, 221 North Grand Boulevard, St. Louis.

Guggenheim Foundation Awards.—The *John Simon Guggenheim Memorial Foundation* has announced its annual award of fellowships. They include the following in the field of the biologic sciences:

Leland S. McClung, Ph.D., instructor in research medicine, Hooper Foundation for Medical Research, University of California, for studies of certain disease-producing and food-spoiling bacteria.
Dr. Henry N. Harkins, instructor in surgery, University of Chicago, for research into the nature and causes of surgical shock.
Alfred George Marshak, Ph.D., Boston, physiologist, for investigation into the mechanism of chromosome division.
Isidore Gersh, Ph.D., instructor in anatomy, Johns Hopkins University School of Medicine, Baltimore, for studies of the intracellular distribution of certain organic compounds.

Special Society Elections.—Dr. James D. Bruce, Ann Arbor, Mich., was named president-elect of the American College of Physicians at the annual meeting in New Orleans March 30. Dr. Oliver H. Perry Pepper, Philadelphia, was installed as president and the following vice presidents were elected: Drs. Allen A. Jones, Buffalo; Gerald B. Webb, Colorado Springs, Colo., and James Morrison Hutcheson, Richmond, Va.——Dr. John J. Morton Jr., Rochester, N. Y., was elected president of the American Society for the Control of Cancer at the annual meeting of the board of directors in New York March 4. George H. Smith, Ph.D., New Haven, Conn., is vice president and Dr. Frank E. Adair, New York, secretary.

Special Itineraries to Biologists' Meeting.—Three separate itineraries have been planned for persons attending the Federation of American Societies for Experimental Biology in Toronto April 27-29. Itinerary number 1, leaving Chicago April 25 at 11:59 p. m., includes a day in Detroit with a trip to the Ford plant and museum. Trip number 2 will leave April 25 at 8 p. m. and trip number 3 Wednesday April 26, 8 p. m. Rates for these all-expense tours represent substantial savings. Those who wish to make the trip must signify their intentions not later than Monday April 17. Further information may be obtained from Dr. Arno B. Luckhardt, department of physiology, University of Chicago, Chicago; telephone: Midway 0800, local 963.

Pan-Pacific Surgical Meeting.—The third congress of the Pan-Pacific Surgical Association will be held in Honolulu September 15-28 under the presidency of Dr. J. Hardie Neil, Auckland, N. Z. Motion pictures will be featured especially at the meeting and those who wish to present films are urgently requested to send them, registered, to Dr. Howard L. Updegraff, chairman of the section on surgical movies, 6777 Hollywood Boulevard, Hollywood, Calif., for technical editing. Among other features will be a hospital institute. The program chairman for the United States is Dr. Frederick L. Reichert, San Francisco. Surgeons interested in obtaining further information may write to Dr. Reichert or to Dr. Forrest J. Pinkerton, Honolulu, secretary of the association.

American Pediatric Society.—The fifty-first annual meeting of the American Pediatric Society will be held April 27-29 at Skytop Lodge, Skytop, Pa. Among the addresses on the program will be:

Drs. Gilbert M. Jorgensen and Henry S. Christian, New York, Treatment of Pneumococcal Infections in Children with Sulfapyridine.
Dr. Edward C. Curnen Jr., Boston, Serum Treatment of Type XIV Pneumonia.
Dr. Henry J. Gerstenberger, Cleveland, Experience with the Use of Phosphate for Treatment of Infantile Rickets.
Dr. Frederic W. Schlutz, Chicago, Physical Fitness of the Child as Reflected by Cardiovascular and Blood Serum Changes During Exercise.
Dr. Joseph Stokes Jr. and Dorothy R. Shaw, Philadelphia, Comparative Studies of the Antibody Response of Individuals Vaccinated with Human Influenza Virus.
Dr. Alfred Hand, Philadelphia, Two Complete Recoveries from Cretinism.
Dr. Irvine McQuarrie and Mildred R. Ziegler, Minneapolis, Experimental Studies Concerning the Pathologic Physiology of Insulin Convulsions.

Dr. Clifford G. Grulee, Evanston, Ill., is president of the society.

Commission on Graduate Medical Education Meets.—"Considerable progress is being made in the clarification of the place of the internship, the residency, the short postgraduate courses and other educational opportunities in the broad field of graduate medical education," declared Dr. Willard C. Rappleye, New York, chairman of the Commission on Graduate Medical Education, following a meeting of the commission in New York City April 1. "With the cooperation of medical and hospital leaders, the commission hopes to offer constructive suggestions regarding needs now existing in the field of graduate medical education and opportunities for developing more adequate educational facilities by medical schools, hospitals, national and local medical organizations and specialty societies. It is felt that the need for more adequate graduate and postgraduate medical training is pressing and has been sharpened by the formation of the twelve specialty boards. It is gratifying to find that interest in these fields is now so widespread that it appears certain that hospitals, medical schools and other agencies will develop satisfactory programs to meet this need in the near future." The commission expects to complete its work within a year and at that time will publish a full report of its observations and conclusions.

National Academy of Sciences.—The annual meeting of the National Academy of Sciences will be held at its headquarters, 2101 Constitution Avenue, Washington, D. C., April 24-25. The speakers on the scientific program include:

Dr. Warren H. Lewis, Baltimore, Changes in Viscosity and Cell Activity.
Karl Sax, Sc.D., Arnold Arboretum, Jamaica Plain, Mass., The Time Factor in X-Ray Irradiation.
Dr. August Krogh, Copenhagen, Denmark, The Active Uptake of Ions by Organisms.
Duncan A. MacInnes, Ph.D., and Lewis G. Longsworth, Ph.D., New York, Electrophoretic Studies in Blood Studies on Blood Sera.
Gioacchino Failla, D.Sc., and Kanematsu Sugiura, New York, Experimental Results Supporting the "Fluid Flow" Theory of the Biological Action of Ionizing Radiations.
Dr. Herbert M. Evans and Gladys A. Emerson, Ph.D., Berkeley, Calif., Degrees of Sterility in the Female Rat Held on E-Free Rations.
Dr. Henry Borsook, Dr. Marshall Y. Kremers and C. G. Wiggins, Pasadena, Calif., Relief of Symptoms in Major Trigeminal Neuralgia (Tic Douloureux) Following the Administration of Massive Doses of Vitamin B Supplemented in Some Instances by Concentrated Liver Extract.
Dr. Walter B. Cannon, Boston, A Law of Denervation.

Warning Against Impostor.—Wake Forest College, N. C., and the University of Pennsylvania School of Medicine, Philadelphia, have reported activities indicating that an impostor is attempting to use credentials of a graduate of the two schools. Herman William Farber, formerly of Weldon, N. C., graduated from Wake Forest in 1930 with the bachelor's degree and from the two year school of medicine in 1932. He then finished his medical course at the University of Pennsylvania, graduating in 1934. In September 1938 both schools received letters signed Herman William Farber and requesting copies of his diplomas because the originals had been destroyed by fire. In addition the letters asked for official transcripts of credits for presentation to state licensing boards. Wake Forest sent the transcripts of Farber's college record, both liberal arts and medicine, to Farber at Evansville, Ind., as he requested. Later he wrote to ask if the Wake Forest officials would affix the college seal to the transcripts. The college agreed to do this but reports that the transcripts were never received. Late in October the duplicate diplomas were sent to Farber in care

of General Delivery at Evansville. The real Dr. Farber is living in Richmond, Va.; he has had his diploma since graduation and has never been in Evansville.

Annual Meeting of Health Officers.—The fifty-fourth annual meeting of the Conference of State and Provincial Health Authorities of North America will be held at the U. S. Public Health Service, Washington, D. C., April 21-22, under the presidency of Dr. Felix J. Underwood, Jackson, Miss. The speakers will include:

Lowell J. Reed, Ph.D., Baltimore, The Standard Million of Population.
Dr. Wilson C. Williams, Nashville, Tenn., Coordination of Health Education Between State Departments of Health and Public Instruction.
Dr. John O. Bower, Philadelphia, Public Health Aspects of Appendicitis.
Dr. Gregoire F. Amyot, Vancouver, B. C., British Columbia Program for Medical Care.
Dr. George C. Dunham, U. S. Army, Typhoid Vaccine, Duration of Immunity, Methods of Administration.
Dr. Wilbur A. Sawyer, New York, The Health Officer's Interest in Virus Diseases.
Dr. Haven Emerson, New York, Current Practice in Communicable Disease Control.
Dr. Eugene L. Bishop, Chattanooga, Tenn., What Constitutes Public Health from an Administrative Standpoint.

Sunday morning April 23, through the courtesy of Col. Joseph F. Siler and Lieut. Col. George C. Dunham, medical corps, U. S. Army, a demonstration of the manufacture of typhoid vaccine and pneumonia vaccine, among other things, will be given at the Army Medical School laboratory.

FOREIGN

Society News.—The fourth World Congress of Workers for the Crippled will convene in London July 16-22 under the auspices of the International Society for Crippled Children and the English Central Council for the Care of Cripples. The program will deal with the industrial cripple, education and preventive orthopedics in childhood. Those desiring accommodation on the convention ship, the S. S. *American Merchant*, may secure space by writing to H. W. Roden, Travel Bureau, Mellon National Bank, Pittsburgh.

Cameron Prize Awarded to Professor Domagk.—The University of Edinburgh has awarded the Cameron Prize for 1939 to Prof. Gerhard Domagk, director of the Institute for Experimental Pathology, I. G. Farbenindustrie, Elberfeld, Germany, for his discovery of the treatment of bacterial diseases by compounds of the sulfonamide group. Dr. Domagk is 43 years old and a graduate in medicine of the University of Kiel. The Cameron Prize, amounting to about £200, is awarded annually to the person who in the opinion of the university senate has in the previous five years made any highly important and valuable addition to practical therapeutics.

Congress on Life-Saving and First Aid.—The fifth International Congress on Life-Saving and First Aid to the Injured will be held in Zurich and St. Moritz, Switzerland, July 23-28. All agencies concerned with life-saving and first aid are invited to send delegates. Eight sections are being organized: rescue work and first aid in catastrophic events and international traffic; first aid to the injured in general; organization of first aid, rescue work and first aid (including protective measures); first aid on the coast and inland waters; first aid at sporting events and the history and idea of life-saving and first aid. The languages of the congress will be French, German, Italian and English. Inquiries should be addressed to the Secretariat of the fifth International Congress for Life-Saving and First Aid to the Injured, Schmelzbergstrasse 4, Zurich, Switzerland.

Missionary Society One Hundred Years Old.—The Canton Medical Missionary Society has been in existence 100 years. Because of the military occupation of the city, commemoration of the centenary has been postponed. The society was founded by three missionaries, two of whom were physicians, in 1838 for the principal purpose of conducting the Canton Hospital, founded three years earlier. A further object was to establish and maintain hospitals and dispensaries throughout China. The present hospital was opened in 1935. At that time also the cornerstone was laid for the Dr. Sun Yat Sen Medical College. During the past year it has cared for hundreds of victims of aerial bombing and is still functioning, though full of poor patients, admitted chiefly from refugee camps, according to a newspaper account. Dr. William W. Cadbury is superintendent of the hospital. The society has constantly worked with the foreign mission boards, which have provided and maintained the physicians to staff its hospitals; present operation of the hospital is made possible by contributions from the International and the American Red Cross.

Gas Masks for Babies

The whole civilian population of the country has been supplied with masks protective against gas attacks from the air, but the problem of producing a mask suitable for young children has proved difficult. After three years of continuous research a mask has been made for children under the age of 2 years. It resembles a helmet and consists of a hood of impervious fabric fitted with a large window of cellulose acetate. The hood encloses the head, shoulders and arms of the child and is closed round the waist by a draw-tape. The baby inside can thus move its arms and put its hand to its mouth—an important point, it was found, in keeping the baby quiet. The hood is surrounded by and fastened to a light metal frame, which is lengthened on the under side and fitted with an adjustable tailpiece as a support and protection for the child's back. The tailpiece is turned up at the end to form a seat, which prevents the child from slipping out of the hood. The child is made secure in the helmet by means of a T shaped supporting strap connected to the end of the tailpiece. The hood is padded on the under side, where the child rests. Air is supplied to the inside of the hood by a rubber bellows. The air passes through a container which removes all poison gas, and it enters the hood at the top through an orifice which deflects it upward so that it sweeps out all vitiated air from the hood and also prevents the stream from blowing directly on the child's head. The space in the hood is large enough to allow pumping to be stopped for several minutes if required. Tests have shown that these masks are worn without inconvenience to the child and that they are effective in an atmosphere of lethal gas. For children between the ages of 2 and 5 years a special mask, similar to that for adults but with modifications introduced for the sake of comfort and further security, is being produced.

A Gestation Period of 174 Days

In the divorce court the fact that the earliest possible date for conception after marriage allowed a maximum of only 174 days for a child who survived birth was given as sole evidence of adultery on the part of the wife. In giving judgment the president said that this was the most remarkable case with which he had had to deal. There was not a shred of evidence that the wife was conducting any sort of association with another man. He quoted from Taylor's textbook, "Principles and Practice of Medical Jurisprudence": "It would be in the highest degree unjust to impute illegitimacy to offspring or want of chastity to parents merely from the fact of a 6 months child being born and surviving birth." He could dispose of the case on that passage, but there was also the evidence of the very experienced midwife that this and one other child were the most extreme cases of premature birth which she had seen in her experience of thirty years. The president was satisfied that the child was conceived in wedlock and dismissed the husband's petition but granted the wife a divorce on the grounds of the husband's adultery. It should be noted that in this case the age of the child at birth was exactly 6 lunar months and therefore less than 6 calendar months.

The Improved Health of the People

In the House of Commons the labor party claimed that malnutrition was prevalent, for which the government should provide a remedy. It may be pointed out that our people are the best fed in Europe and that the expenditure on the social

services, which include free meals for school children, is enormous. In the debate it was stated that the purchasing power of the working class was four times what it was at the time of the battle of Waterloo. Mr. Elliot, minister of health, said that the government had introduced the subject of nutrition into national discussion and had taken action in the light of the newer knowledge. The consumption of milk by school children had gone up and they were keeping up pressure on agriculturists to insure a pure supply. The following statistics showed the extent to which malnutrition was being repelled. In 1927 infant mortality was 70 per 1,000 and today it was 58; maternal mortality was 4.11 per 1,000 against 3.26 today. Maternal mortality from puerperal sepsis had fallen from 1.97 in 1927 to 0.98. The tuberculosis mortality had fallen from 79 in 1927 to 56 today. All indications pointed to an improvement in nutrition of children. A comparison between 1927 and 1937 showed that boys in Leeds were more than 1 inch (2.5 cm.) taller and 3½ pounds (1.5 Kg.) heavier and in Huddersfield were 1½ inches (3.7 cm.) taller and more than 5 pounds (2.5 Kg.) heavier.

PARIS

March 11, 1939.

Treatment of War Injuries Accompanied by Severe Hemorrhage

At the February 14 meeting of the Académie de médecine of Paris, two leading army surgeons, Maissonet and Barthélemy, reviewed recent progress in the treatment of certain types of war injuries. A severe hemorrhage can threaten life under one of three conditions: 1. An artery of medium caliber is divided, but, during a battle, the injured soldier cannot be transported immediately and the bleeding continues for several hours, until extreme anemia supervenes. 2. An artery of large caliber is sectioned. Even though immediate care is given in both these forms of injury, the wound is either fatal or the soldier is found exsanguinated. 3. Multiple injuries to soft parts are individually of minor importance but the sum total is such that the soldier is found in an extremely anemic state. The treatment of these three types of injuries should be both local and general. As to the first, if an artery of moderate caliber in an extremity has been divided, after application of a tourniquet on the proximal side the soldier should be sent to the nearest casualty clearing station for more thorough treatment. If a large artery of an extremity has been sectioned, the only hope is that some one can close the opening digitally until a tourniquet is applied. For use in case of injury to a large artery of the neck, every front line surgeon should be provided with a set of sterile instruments for opening the wound and applying forceps to the bleeding vessel preparatory to transportation of the wounded man behind the lines. Many lives can be saved by this procedure. In the case of multiple wounds none of which involve an artery or vein of any importance, only firm compression with dressings is indicated, because treatment of multiple injuries at the front involves too much shock.

The general treatment includes blood transfusion and serotherapy. These should be employed only at a casualty clearing station equipped with facilities to permit care of the wounds at the same time. The use of citrated refrigerated blood is the only feasible method of transfusion except during a battle with sudden changes of the front lines, when it may be difficult to reach the injured with automobiles or airplanes carrying the conserved blood. During the Spanish war it was found that conserved blood was invaluable except during offensives and periods of instability of the front lines. By serotherapy is understood here the replacement of the blood which has been lost by the intravascular injection of artificially prepared substitutes, such as saline or acacia solutions. The disadvantages of the saline solutions are that they lack viscosity and osmotic pressure, the latter because of an insufficient quantity of colloids. Sherrington and Copeman have shown that saline solutions leave the circulation in less than an hour and a half after injection. Normet in 1929 proposed the addition of small quantities of the citrates of sodium, calcium, magnesium, iron and manganese to a 0.9 per cent saline solution. Gosset, Tzanck and Charrier (*Presse médicale,* Dec. 20, 1930, p. 1745) found that Normet's polycitrate solution, although not a substitute for blood, was not excreted as rapidly as physiologic solution of sodium chloride.

The best substitute for blood transfusion has been found to be injection of acacia solution as proposed by Bayliss; this solution is retained in the vessels long enough to enable the blood-forming organs to begin to function. Blood transfusion or, if no blood is available, injection of physiologic solution of sodium chloride or the Bayliss solution should be performed simultaneously with and not before local hemostasis. Every casualty clearing station should have an ample supply of flasks containing either the sterilized Normet polycitrate solution or the Bayliss acacia solution. In addition, every such advance center should have ready, as soon as an offensive begins, a supply of conserved refrigerated blood susceptible of being utilized within eight days of its collection from civilian donors as explained in a previous letter.

Sulfanilamide for Meningococcus B Meningitis

A case was reported at the January 20 meeting of the Société médicale des hôpitaux of Paris by the navy surgeons Germain and Gautron in which recovery from meningitis due to meningococcus B followed the use of sulfanilamide. A sailor aged 42 presented the typical clinical picture of meningitis. Cultures of the cerebrospinal fluid revealed the presence of meningococcus B. Without waiting for the results of the examination of the spinal fluid, the patient was given sulfanilamide immediately on admission to the hospital, at first 8 Gm. daily by mouth. During the first three days and again on the fifth day, from 20 to 30 cc. of an 0.8 per cent solution was given intraspinally. Altogether, 107 Gm. of sulfanilamide was given. Twenty-four hours after treatment was begun there were a drop in the temperature and a decrease in the headache and somnolence. At the end of forty-eight hours the temperature was normal, there was less rigidity of the neck and cultures of the spinal fluid were sterile. The only complication was a slight cyanosis of forty-eight hours' duration. Recovery was complete eighteen hours after the beginning of treatment.

Death of Dr. Antoine Béclère

The dean of French radiologists, Dr. Antoine Béclère, died February 25 in Paris at the age of 82. About a year after the discovery of the x-rays Béclère was present during a radioscopic examination for suspected pulmonary tuberculosis. He immediately foresaw the future of this new method of diagnosis and began to devote his energies to its clinical application, being one of the first to recommend the use of a dark room and of a fluoroscope in the examination of lesions of the chest. He soon extended the roentgen method to the diagnosis of pathologic changes in other viscera and then began to study the effects of roentgen therapy on neoplasms. He was elected a member of the Academy of Medicine of Paris as a recognition of his contributions to the development of roentgenology. During the World War Dr. Béclère was in charge of a school in which radiologists were trained for service in army hospitals. After the war and until a few weeks before his death, he took a vigorous part in the activities of the various medical societies in France and foreign countries. He suggested the use of iodized oil as an opaque medium in

the diagnosis of uterine and tubal lesions. During the past twenty years he had become interested in the relation of ovarian and testicular tumors to the hypophysial hormones and in many other research problems. In 1936 many of his former pupils met to celebrate the eightieth birthday of this untiring worker, who until a few days before his death was busy editing a paper on experimental studies at the Radium Institute of Paris. In addition to serving a term as president of the Academy of Medicine, the leading society here, Dr. Béclère was an honorary member of many French and foreign medical organizations.

The Quinine-Calcium Treatment of Pneumonia

Professor Kalk, a pupil of Professor von Bergmann and director of a large Berlin hospital, recently discussed the quinine-calcium treatment of pneumonia before the Berlin Medical Society. The pneumonia mortality has at present come to exceed that of tuberculosis; in many hospitals every fifth patient and in some instances every second patient succumbs to the disease. Moreover, as it is now seventeen years since the introduction of quinine therapy by von Bergmann, comparison of this method with serotherapy has become possible. Within the past four years Kalk has observed more than 2,000 cases of pneumonia. The picture often varies according to the age group; bronchopneumonia preponderates among children, lobar pneumonia is most important among younger adults, whereas bronchopneumonia again comes to the fore among the elderly. This linear scheme may be extended into the immunobiologic circular scheme of the negative and positive anergy. Kalk regards pneumonia as a secondary illness; in virtually all his cases a meticulous study disclosed the history of some infection, such as a mild influenza or a cold, which had been manifested from two to three weeks previously. When later the patient experienced chills, the earlier, minor disturbance would tend to be forgotten. This circumstance suggests the concept of nonspecific sensitization, as developed by von Bergmann and the Berlin pathologic anatomist Professor Rössle.

Kalk discussed the influence of weather on the pneumonias and reported observations of the interrelation of normal atmospheric temperature and relative humidity. If the temperature is lowered and the moisture content of the air is high (as in oceanic drops in temperature originating in the west) the pneumonic morbidity curve will exhibit a sharp upturn, conditioned by the great concomitant deprivation of heat; the coolness of the weather may be still further enhanced by strong winds. The author found that vitamin C deficiency increases susceptibility to pneumonia and acts unfavorably on the course of the disease.

Professor Kalk himself has had pneumonia six times and in three of these instances cut short his illness by the use of quinine. He is a confirmed advocate of parenteral quinine therapy combined with the administration of calcium. If utilized in time, this procedure bids fair not only to arrest the pneumonia but also to inhibit infiltration. If infiltration is already present, the procedure appears as a rule to induce earlier resolution. Parenteral quinine-calcium therapy is thus effective at times when the use of quinine alone does not suffice. Kalk was able to obtain like results in bronchopneumonia by the utilization of similar quinine preparations.

The pneumonia mortality among Kalk's clinical material has shown a decline of from around 23 per cent to 16 per cent since the utilization of quinine-calcium preparations. In army hospitals, according to the latest reports, the decline has been from 9.8 per cent to 4.9 per cent. The army figures provide the best possible illustration of how effective this therapy can be if it is introduced in the initial stage of the illness; this timely treatment is particularly feasible in the army, thanks to the highly efficient organization of the medical corps. Kalk discusses reports of lesions allegedly caused by quinine therapy. He considers the use of the term "lesions" here unjustifiable. In a total of 60,000 injections of quinine only seven, according to the author's observations, were followed by the formation of an abscess; in addition, paralysis of the peroneal muscles was observed in but one instance. From the foregoing data it will be seen that in view of the enormous advantage of this therapy one cannot correctly speak of it as "dangerous." As to serotherapy, Kalk simply remarks that, although at present thirty-two different strains of pneumococci are differentiated, thus far the mortality has been lowered only in cases based on types I and II, and then never by as much as 50 per cent. For this reason as well as on account of the greater expense involved, the author feels unwilling to recommend serotherapy. It would seem that Kalk has never carried on any large scale studies of serotherapy, such as would form a true basis for comparison. But even in the absence of a comparative evalution his data on the favorable results of quinine-calcium therapy are still interesting.

AUSTRALIA

March 1, 1939.

The Association for the Advancement of Science

The twenty-fourth biennial meeting of the Australian and New Zealand Association for the Advancement of Science was held in Canberra January 11-18. Attracted by the unique circumstances of meeting at the federal capital and by the fact that the association executive had succeeded in securing the presence of several overseas notables, a record membership of 1,200 delegates attended the meeting. Overseas visitors included Prof. Ralph Carr and Dr. Anita Muhl, representing the American Association for the Advancement of Science; Prof. F. T. Brooks, representing the British Association; Sir E. John Russell, Rothampstead Agricultural College; Prof. N. V. Sidgwick (Cambridge), noted chemist; Sir John Flett, Sir George Simpson and Mr. H. G. Wells. The sections represented were mathematics, physics, astronomy, optometry, geology, zoology, history, anthropology, economics, statistics and social science, engineering and architecture, medical science and national health, education, psychology and philosophy, agriculture and forestry, veterinary science, botany, physiology, pharmaceutic science, geography and oceanography. The congress was perhaps disappointing to the extent that little official attempt was made to relate the discoveries of science to the personal experience of everyday life and no constructive recommendation of any social significance emerged from it.

THE AUSTRALIAN JOURNAL OF SCIENCE

The Australian National Research Council, which was derived from the association some years ago, has, after a period of independent existence, now become in effect a committee of the association. The council has commenced the publication of a journal of the type of *Nature*. This journal now appears bimonthly as the *Australian Journal of Science*. The journal aims to cover a field including short advance summaries of research, periodic accounts of recent work in various branches of science, book reviews, proceedings of scientific societies, doings in Australian universities and museums, current news, personal information and correspondence.

HEART SIZE IN RELATION TO EXERCISE

Dr. Fritz Duras, director of physical education in the University of Melbourne, submitted a paper on heart size in relation to exercise. He discussed the results he had obtained from the

measurement of heart size after various types and intensities of exercise. Measurements were made of the lateral diameter on a fluoroscopic screen. He had found that heart size decreased during static work, increased during moderate dynamic work and increased only slightly, if at all, during more strenuous work. After exercise the size of the heart fluctuated about a continually increasing mean size and might not return to preexercise measurement for forty-eight hours. He also considered the possibility of complete relaxation of heart muscle being prevented by fatigue. The normal heart could not be damaged even by the most strenuous exercise but the normality must be established by proper medical examination.

MAXIMUM POWER OF HUMAN WORK

Considering the maximum power of human work, Dr. F. S. Cotton of Sydney has found champion cyclists to be able to work for five minute periods at rates in excess of one-half horse power. These figures are materially higher than the highest recorded figures for this period of work, namely those of Olympic oarsmen, in spite of the fact that the latter figures included a somewhat arbitrary allowance for work not used in propelling the boat.

TISSUE INJURY BY RADIANT ENERGY

Drs. C. H. Kellaway and E. R. Trethewie reported the results of recent experiments carried out at the Walter and Eliza Hall Institute, Melbourne. Injury by radiation caused the isolated lung preparation to liberate histamine in a manner similar to a number of pharmacologically active substances, such as venoms and peptone. The injurious effect of light on tissues sensitized by dyes was not confined to regions normally exposed to radiation. Histamine was destroyed by photodynamic action in the presence of oxygen, as for instance in suspensions of ground lung tissue, when the histamine content disappeared on exposure to light. The response of histamine of an isolated jejunum preparation of a guinea pig sensitized with hematoporphyrin protoporphyrins rapidly diminished on exposure to light. Methylene blue caused increased sensitivity of the intestine to histamine in the dark; in bright illumination the effect rapidly diminished. Eosin had a slow contracting effect on the intestine, which in bright illumination failed to relax readily following histamine contractions. The injury to muscle cells in these experiments was such that they failed to respond to the histamine, which was almost certainly set free and which might also have been destroyed by photodynamic action.

CHEMISTRY OF HEMOGLOBIN METABOLISM

In a paper on the chemistry of hemoglobin metabolism, Dr. R. Lemberg of Sydney said that it had heretofore been assumed that hematin and porphyrin were intermediate products in the change from hemoglobin to bile pigments, the removal of protein being followed by that of iron and the porphyrin transformed into bilirubin. It could now be shown that the real intermediate products were bile pigment-hematin compounds and biliverdin, the oxidative opening of the porphyrin ring occurring before the removal of protein and iron. The reaction began with the hydrogenation of oxyhemoglobin. Among the intermediate compounds were those with "easily detachable iron." Finally, biliverdin was reduced by dehydrogenase systems to bilirubin. In the intestine bilirubin was reduced to urobilin. The iron from the bile pigment-hematin compounds was used for the synthesis of hemoglobin, but nothing was known about the synthesis of the porphyrin ring in the animal body. In different circumstances oxidations might occur at the side chains and not on the porphyrin nucleus. Under these conditions biologically important catalysts might be formed.

Dr. Lemberg exhibited his own preparations of many of the blood pigments and their intermediate products.

SYMPOSIUM ON ANIMAL PIGMENTS

Contributing to a symposium on animal pigments, J. W. Legge of Sydney discussed the physiologic disintegration of hemoglobin in the animal body. He supported Lemberg's theory and presented evidence for the formation of intermediate bile pigment-iron-protein by oxidation of the a-methene bridge of the porphyrin molecule of hemoglobin. With choleglobin, the best known of these compounds, reversible combination with oxygen and carbon monoxide could be observed spectroscopically. By action of ascorbic acid on hemoglobin in air a second similar compound was formed. Both compounds occurred in normal erythrocytes and were formed when blood containing dissolved hemoglobin was perfused through the spleen, or after in vivo hemolysis by the action of distilled water, arsine or phenylhydrazine. From these intermediate compounds, removal of iron and protein gave biliverdin. Both dehydrogenases could reduce this to bilirubin.

VIRUS ACTIVITY OF SOME PROTEIN MOLECULES

R. J. Best of Waite Institute, Adelaide, described his recent work which had resulted in the separation of certain viruses in a chemically pure state and had demonstrated that they were proteins. He showed evidence for the identity of protein and infective principle in the case of certain plant viruses and described some aspects of the gross physical structure of the virus as revealed by x-ray analysis and optical means. He mentioned a few of the properties of viruses most likely to influence biologic activity and touched on problems relating to strain variation, mutation and possible methods by which viruses might multiply. The virus molecules built themselves into long chains, quite readily visible microscopically in polarized light. These chains were readily broken up mechanically but on standing they formed again. In subsequent discussion it was considered questionable whether the purified virus proteins could be regarded as crystals, as they were only two dimensional. True crystals on the other hand were characterized by definite angles between faces in three planes. The multiplication of virus could not be considered apart from its association with the host. It was built on the cell mosaic of the host cell. It was doubtful whether the increase of virus protein in infected cells could be regarded as a multiplication of these protein molecules. It might be considered that the virus modified the metabolism of the cell in such a way that some virus protein was produced by it in place of its normal protein. It was also suggested that the virus might be regarded as a proteolytic enzyme which, acting on the cell proteins as substrate, produced from them virus protein as one of the products of its action.

Marriages

LAURA C. GAETJENS, Oradell, N. J., to Mr. J. Perry Morris of Norfolk, Va., in Pensacola, Fla., February 19.

EDGAR GILMORE GIVHAN JR., to Miss Margaret Woodward Spencer, both of Birmingham, Ala., February 22.

JAMES B. GILLESPIE, Urbana, Ill., to Mrs. Emily Reeve of Paxton, in San Antonio, Texas, February 27.

CARL NORMAN GIERE, Minneapolis, to Miss Helen Louise Butler of Fort Sill, Okla., January 27.

EDWARD HUMPHREYS HERRING to Mrs. Lucile Sherrod Collins, both of Raleigh, N. C., January 7.

PAUL HAYNE CULBREATH JR., Ellenton, S. C., to Miss Sara Miller of Hodges, Dec. 29, 1938.

PHILIP H. NIPPERT, Atlanta, Ga., to Miss Lucille Garrison of Miami, Fla., February 8.

LEWIS KARL HOHERMAN to Miss Esthermae Bogan, both of Philadelphia, recently.

SOL NEIDICH to Miss Evelyn Rudowitz, both of Beaufort, S. C., Dec. 25, 1938.

JOHN S. HAINES, Baltimore, to Miss Clara Elizabeth Ward, January 14.

Deaths

William Hallock Park ⊕ *eminent as a medical contributor* to the field of public health and noted as a bacteriologist and immunologist, died in New York April 6 of heart disease. Dr. Park was born in New York Dec. 30, 1863. After graduation from the College of the City of New York in 1883 he received the degree of doctor of medicine at Columbia in 1886. Following three years of internship at Roosevelt Hospital he went to Vienna during 1889-1890, returning to New York to take up practice as a specialist in diseases of the nose and throat. While engaged in this work he carried on research at the College of Physicians and Surgeons, concerning himself particularly with diphtheria. This work commanded the attention of Dr. Hermann M. Biggs, who at the time was professor of bacteriology and hygiene at New York University and also in charge of one of the divisions of the New York City Health Department. Dr. Park was appointed bacteriologic diagnostician of diphtheria in the city health department and director of its research laboratory in 1894. There the first municipal bacteriologic laboratory in the United States was organized. The methods of diagnosis, control and prevention of communicable disease originated under Dr. Park have since been adopted throughout the world. For forty-two years, until the time of his retirement, Dr. Park continued his labors as active head of the public health laboratory, serving as consulting bacteriologist to the New York State Department of Health from 1914 onward, medical examiner in bacteriology from 1917 and consulting bacteriologist at the U. S. Quarantine Service from 1921.

In 1898 Dr. Park was appointed adjunct professor of bacteriology and hygiene at the New York University; in 1899 he became associate professor and in 1900 professor, holding this position until 1933, when he became first incumbent of the Biggs chair of preventive medicine. For one year he served as dean of the medical college. From 1895 to 1932 he was visiting bacteriologist to the Willard Parker Hospital and later served as consultant. In 1910 he received the honorary LL.D. degree from Queens University. In 1926 he was awarded the degree of doctor of science by New York University, in 1929 by Yale University and in the same year by Columbia University. During his career he also received many honors such as the Public Welfare Medal of the National Academy of Sciences in 1932 and the George M. Kober Medal of the Association of American Physicians in 1937. In 1933 he received also the Townsend Harris Medal for his achievements in medicine. In 1935 he received the Roosevelt Medal because of his contributions to the control of diphtheria. On his seventy-first birthday, Dec. 30, 1934, his assistants in the New York City Department of Health presented him with a bronze bas relief plaque of himself to be placed in the Willard Parker Hospital. When the William Hallock Park Laboratory, named and dedicated in his honor in 1936, was established President Franklin D. Roosevelt wrote him a letter in which he said, "Your contribution to medical progress will continue to benefit the people of New York, of this nation and of the world long after this splendid laboratory has crumbled to dust."

From time to time Dr. Park was called to deliver lectures before famous organizations. Thus he gave the Nathan Louis Hatfield lectures of the College of Physicians of Philadelphia in 1935. He received the Achievement Award of the Columbia Alumni Association of the Graduate Schools in 1934. In 1933, at a great celebration, he immunized against diphtheria the millionth child to be inoculated in New York City, the first of the second million being immunized by Dr. Béla Schick. When it was proposed to develop a method of inoculation against infantile paralysis in 1934, he voluntarily submitted himself to be one of the first three injected.

Dr. Park was a frequent contributor to medical literature. His works included "Pathogenic Micro-Organisms," of which the tenth edition appeared in 1933; "Public Health and Hygiene" in 1927; "Who's Who Among the Microbes" in 1929. Among the research problems to which he turned his attention in addition to methods of immunization against diphtheria were the character of the tubercle bacillus, the nature of dysentery, the typhoid bacillus and typhus carriers, intraspinal injection of tetanus antitoxin, the bacteriology of respiratory infections and the treatment of pneumonia.

He was a member of most of the leading societies in the fields of his scientific interest, and he had served as president of the American Society of Experimental Pathology and of the American Public Health Association. His death at the advanced age of 75 terminated a career of great importance and of vast benefit to the people and the medical profession of our country.

WILLIAM HALLOCK PARK, M.D., 1863-1939

Donald Gregg ⊕ Wellesley, Mass.; Harvard University Medical School, Boston, 1907; fellow of the American College of Physicians; member of the American Neurological Association, American Psychiatric Association, New England Society of Psychiatry, Association for Research in Nervous and Mental Diseases and the American Psychopathological Association; president of the Massachusetts Society for Mental Hygiene; instructor in physical diagnosis, 1910, and assistant professor of tropical medicine in 1911 at the University of the Philippines, Manila; medical superintendent of the Channing Sanitarium; aged 58; died, January 6, in Massachusetts General Hospital.

Leonard Woolsey Bacon, New Haven, Conn.; Yale University School of Medicine, New Haven, 1892; member of the Connecticut State Medical Society; served during the World War; assistant in medical clinic 1892-1894, assistant in surgical clinic 1895-1897; instructor in operative surgery 1897-1905 and instructor in surgery 1905-1906 at his alma mater; for many years on the staff of the Grace Hospital; aged 73; died, January 8, of arteriosclerosis at his home in Hamden.

Henry Corbin McClenahan, San Francisco; Tulane University of Louisiana School of Medicine, New Orleans, 1895; member of the California Medical Association; veteran of the Spanish-American War; at one time assistant in clinical neurology and associate to the chair of legal medicine and psychiatry, Cooper Medical College; aged 67; died, Dec. 11, 1938, of arteriosclerosis, myocarditis and hypertension.

William Cott Hobdy ⊕ San Francisco; Columbia University College of Physicians and Surgeons, New York, 1896; formerly connected with the U. S. Public Health Service; on the staffs of the Stanford University and Franklin hospitals; aged 68; died, Dec. 26, 1938, of carcinoma of the liver with metastases.

Emil Gustave Winter, Indianapolis; Eclectic Medical Institute, Cincinnati, 1907; Indiana University School of Medicine, Indianapolis, 1908; served during the World War; formerly county deputy coroner; aged 52; on the staff of the Methodist Hospital, where he died, Dec. 18, 1938, of acute coronary occlusion.

William Gray Thigpen, Montgomery, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; member of the Medical Association of the State of Alabama; served during the World War; aged 59; died, Dec. 11, 1938, in the Veterans Administration Facility, Biloxi, Miss., of pneumonia.

Nicholas De Haas, Fremont, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; past president of the Newaygo County Medical Society; aged 68; was chief of staff, 1916-1917 at the Gerber Memorial Hospital, where he died, January 18, of carcinoma of the stomach.

Robert Hubert Fegers, Keokuk, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1906; member of the Iowa State Medical Society; aged 55; on the staffs of the Graham Protestant Hospital and St. Joseph's Hospital, where he died, Dec. 26, 1938.

Harry Joseph McGuire, Tulsa, Okla.; Rush Medical College, Chicago, 1926; member of the Oklahoma State Medical Association; formerly city health superintendent; on the staff of the Morningside Hospital; aged 38; died, Dec. 24, 1938, of cerebral hemorrhage.

William Henry Robin, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1891; member of the Louisiana State Medical Association; formerly health officer of New Orleans and Orleans Parish; aged 69; died, February 9, of heart disease.

John Henry Carpenter ⊕ Chicago; National Medical University, Chicago, 1901; member of the Radiological Society of North America; at one time x-ray technician to Cook County Hospital; aged 65; died, January 18, of carcinoma of the esophagus.

Samuel Walter R. Langdon ⊕ Stockton, Calif.; University of California Medical Department, San Francisco, 1900; formerly health officer; on the staff of the Stockton State Hospital; aged 65; died, Dec. 30, 1938, of cardiovascular renal disease.

John Thomas Dawson, Seattle; Toledo Medical College, 1895; member of the Washington State Medical Association; veteran of the Spanish-American War; on the staff of the Providence Hospital; aged 65; died, January 12, of coronary thrombosis.

Alonzo Wells Connor, Neeses, S. C.; Medical College of the State of South Carolina, Charleston, 1895; formerly member of the state legislature; aged 67; died, January 2, of diabetes mellitus, cardiac insufficiency and prostatitis.

Frank R. Ross, Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1897; member of the State Medical Association of Texas; aged 63; died, Dec. 4, 1938, in a local hospital of lung abscess.

Charles Clary Rathbone, Los Angeles; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; aged 73; died, Dec. 27, 1938, of chronic myocarditis and arteriosclerosis.

Frank Cyril Barltrop Campbell, Owen Sound, Ont., Canada; University of Toronto Faculty of Medicine, 1921; at one time health officer of Henderson and Pulaski counties, Ky.; aged 40; died, Dec. 3, 1938.

John Henry Shipley, Rippey, Iowa; Drake University Medical Department, Des Moines, 1889; member of the Iowa State Medical Society; aged 72; died, Dec. 10, 1938, of valvular heart disease.

Edwin Augustus Kuhns, Emlenton, Pa.; Jefferson Medical College of Philadelphia, 1884; aged 80; died, Dec. 16, 1938, of carcinoma of the ascending colon with involvement of the liver.

Charles L. Reading, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 68; died, Dec. 14, 1938, in the Allentown (Pa.) State Hospital, of chronic myocarditis.

Jerry Calvin Falvey, Longview, Texas; Memphis (Tenn.) Hospital Medical College, 1911; aged 52; died, Dec. 19, 1938, in the Wilson Memorial Hospital, Johnson City, N. Y., of endocarditis.

David Louis Axilrod, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; aged 61; died, January 14, in the Asbury Hospital of cerebral hemorrhage.

George Krauss, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1896; served during the World War; on the staff of the Allentown Hospital; aged 65; died, Dec. 30, 1938, of myocarditis.

Orville Leon Hanlon ⊕ Ridlonville, Maine; Medical School of Maine, Portland, 1901; past president of the Oxford County Medical Society; aged 63; died, Dec. 10, 1938, of coronary thrombosis.

James Edward Stubbert, Oakland, Calif.; University of the City of New York Medical Department, 1881; aged 79; died, Dec. 3, 1938, of myocarditis, arteriosclerosis and prostatic obstruction.

Perry Lee Atkins, Grants, N. M.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; aged 61; died, January 27, in a hospital at Albuquerque, of lobar pneumonia.

Caswell H. Jennings, Wheatland, Ind.; Medical College of Indiana, Indianapolis, 1895; formerly coroner of Greene County; aged 67; died, Dec. 25, 1938, in Terre Haute of coronary occlusion.

William Raney Black, Seminole, Okla.; Chattanooga (Tenn.) Medical College, 1906; member of the Oklahoma State Medical Association; aged 60; died, Dec. 22, 1938, of angina pectoris.

John Edward Brinkman ⊕ Waterloo, Iowa; Illinois Medical College, Chicago, 1898; past president of the Black Hawk County Medical Society; aged 64; died, Dec. 23, 1938, of angina pectoris.

Ephraim G. McCormick, Prairie Grove, Ark.; Missouri Medical College, St. Louis, 1881; member of the Arkansas Medical Society; aged 83; died, Dec. 12, 1938, of cerebral hemorrhage.

Fred Augustus Bragdon, Springvale, Maine; Medical School of Maine, Portland, 1883; member of the Maine Medical Association; aged 80; died, January 24, of carcinoma of the liver.

George McGehee Stewart, Covington, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; aged 76; died, Dec. 27, 1938, in Jackson of arteriosclerosis.

William H. Cowell, Shawboro, N. C.; Kentucky School of Medicine, Louisville, 1893; aged 68; died, Dec. 27, 1938, of chronic myocarditis and hypertrophic cirrhosis of the liver.

Reno N. Williams, Sanders, Ky.; Hospital College of Medicine, Louisville, 1898; member of the Kentucky State Medical Association; aged 77; died, Dec. 26, 1938, of heart disease.

Harvey Albert Dever, El Reno, Okla.; Medico-Chirurgical College of Kansas City, Mo., 1904; aged 64; died, Dec. 25, 1938, in St. Anthony's Hospital, Oklahoma City, of pneumonia.

George Adelbert Delamater, Butler, Mo.; Chicago Homeopathic Medical College, 1893; aged 73; died, Dec. 22, 1938, in South Winter Haven, Fla., of coronary thrombosis.

William V. Marshburn, Yorba Linda, Calif.; University of Louisville (Ky.) Medical Department, 1886; aged 83; died, Dec. 14, 1938, of hypostatic pneumonia and uremia.

Elmer D. Shadday, Montpelier, Ind.; Kentucky School of Medicine, Louisville, 1901; county health officer; aged 65; died, Dec. 19, 1938, of coronary sclerosis and myocarditis.

Edward V. Cherney, Springfield, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1903; aged 57; died, January 27, of Parkinson's disease.

Francis X. McPhillips, Vancouver, B. C., Canada; Manitoba Medical College, Winnipeg, 1889; formerly on the staff of St. Paul's Hospital; aged 72; died, Dec. 23, 1938.

Albert Charles McGeagh, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1902; aged 63; died, Dec. 22, 1938, of coronary thrombosis.

Abraham L. Thomas, Chicago; Chicago Medical College, 1879; member of the Illinois State Medical Society; aged 88; died, Dec. 19, 1938, of carcinoma of the stomach.

Charles Solomon Cantough, Reading, Pa.; Jefferson Medical College of Philadelphia, 1914; aged 47; died, Dec. 16, 1938, in St. Joseph's Hospital of coronary thrombosis.

Hugh McCormick, New Auburn, Wis.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1892; aged 72; died, Dec. 17, 1938, of coronary thrombosis.

Charles Luther Kirtley, Challis, Idaho; Rush Medical College, Chicago, 1901; aged 65; died, Dec. 1, 1938, of coronary occlusion, nephritis and arteriosclerosis.

George Nicholas Vogelei, Chicago; Chicago College of Medicine and Surgery, 1913; aged 50; died, Dec. 27, 1938, of angina pectoris.

Henry W. Partlow, Olympia, Wash.; Detroit College of Medicine, 1893; aged 75; died, Dec. 4, 1938, of carcinoma of the sigmoid.

Caleb E. Carter, Tenaha, Texas; Memphis (Tenn.) Hospital Medical College, 1902; aged 69; died, January 15, of pneumonia.

William Lages, Fredericktown, Mo.; Missouri Medical College, St. Louis, 1891; aged 76; died, Dec. 19, 1938.

Samuel W. Downing, Salem, Mo.; Missouri Medical College, St. Louis, 1894; aged 68; died, Dec. 9, 1938.

Herbert Charles Fry, Brooklyn; Long Island College Hospital, Brooklyn, 1898; died, Dec. 4, 1938.

Correspondence

PRIORITY IN TECHNIC FOR PRESERVATION OF SERUM

To the Editor:—In THE JOURNAL, January 14, page 134, Dr. Leon Friedman stated that "Riehl and Schereschewsky in 1919 were the first to use glass capillary pipets, sealed by fusing in a flame, to preserve specimens of serum" for examination of Spirochaeta pallida.

I have seen priority in this useful method of preserving specimens containing Spirochaeta pallida credited to so many workers that I am at last impelled to state that I first used it in 1909 at the Military Hospital, Rochester Row, London, for preservation of specimens for teaching purposes, and it was described and illustrated in my "Diagnosis and Treatment of Venereal Diseases in General Practice," first published in January 1918.

In connection with the observation of Riehl, quoted by Dr. Friedman, that in such conditions Spirochaeta pallida remained motile up to fourteen days after collection, it may be of interest to recall that this time was greatly exceeded in experiments reported by McNabb and his associates (*Canad. Pub. Health J.* **24**:405 [Sept.] 1933) and by myself (*Lancet* **1**:156 [Jan. 20] 1934). To state the case as briefly as possible, the Canadian workers initiated an experiment to test whether transportation over long distances in capillary tubes would be practicable for specimens to be examined for Spirochaeta pallida by the dark-ground method. The specimens were collected in triplicate in London and sent first to Toronto, where motile spirochetes were found. Three were returned to me with one specimen collected in Toronto, and motile spirochetes were again found in all of them. I returned them to Toronto, sealed with wax between slide and coverslip, and after examination in Toronto the same slides were returned to me; motile spirochetes were still found in them both in Toronto and in London. Thus three specimens of chancre fluid crossed the Atlantic four times and one three times, and after these journeys the spirochetes in them were still motile. The lapses of time from the taking of the respective specimens to my last report to the Toronto workers were eighty days, seventy-one days, sixty-eight days and forty-six days. Actually after dispatch of this report motility continued to be noted in one specimen up to the eighty-fourth day after collection.

Dr. Friedman mentions that his specimens were expelled from the tubes by pressure from a small rubber bulb. I suggest that a much easier method is to heat the blind end of the tube in a small flame.

L. W. HARRISON, London, S.W. 1, England.
68 Eccleston Square.

DANIEL DRAKE—INFORMATION, PLEASE, ABOUT LETTERS WRITTEN BY HIM

To the Editor:—For more than twelve years I have been engaged in the preparation of a bibliography of Daniel Drake. The list of published writings is apparently almost completed. Some manuscript material and many letters have already been located. However, Daniel Drake was a voluminous letter writer, and undoubtedly there must be many letters in private hands or in libraries. I shall sincerely appreciate information concerning any letters or manuscript material by Daniel Drake. Due credit will be given in the published work, which will not go to press for several months.

EMMET FIELD HORINE, M.D., Louisville, Ky.
Associate Professor of Clinical Medicine, University of Louisville School of Medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

GOLD FOR TUBERCULOSIS

To the Editor:—I note in my December 2 issue of the *Iowa State Register* an article regarding the care of tuberculosis with a gold solution. Gold has been used in the treatment of tuberculosis all through the years of my fifty years of practice. Would you please advise me whether this solution has been found of real value and now a real cure for this disease. It would seem strange that Dr. Kime of Fort Dodge, Iowa, should find it necessary to go to far away India to publish a complete digest of this material and its methods of use in the Bombay, India, *Medical Digest*. It is also said that this method has been in part revealed by British and American medical journals. I am anxious to know whether this treatment has been found real and a cure for the tuberculosis victim. Would you please let me hear from you.

M.D., Iowa.

ANSWER.—Gold has been used in the treatment of various diseases for approximately twelve hundred years and for more than three centuries it has been employed intermittently in the treatment of tuberculosis. Interest in the gold treatment was revived in 1915. Experimental work as well as the treatment of patients with gold salts revealed the fact by 1920 that their administration is not always safe for the patient and that apparent benefits were due to hyperemia in the vicinity of the tuberculous lesion. There being no accurate method of controlling the degree of hyperemia, the reactions could be sufficiently severe to cause pulmonary hemorrhage.

In 1924 Møllgaard presented the results of some experimental work with a gold preparation known as *sanocrysin*. Since that time a large volume of work has been done with gold salts both experimentally and clinically. One of the most extensive studies conducted on tuberculous patients in this country was by Henrichsen, Sweany and Hruby of Chicago, whose following conclusions represent a fair statement of the present status of the gold treatment for tuberculosis:

"1. About 50 per cent of tuberculous patients having a stationary or downward progressive advanced tuberculosis of the B or C types, when given sanocrysin in well regulated doses, will show (1) a rather prompt cessation of symptoms (drop of temperature and pulse, increase of weight and improvement of general condition), which changes tend to be permanent if the patient observes the usual measures of hygiene; (2) a clearing of tuberculous infiltration, with marked fibrosis and contraction of cavities, as shown by roentgenograms; and (3) changes from unfavorable laboratory findings.

"2. The remainder of the treated patients may be divided about equally into three classes: Those who show a temporary improvement for a few weeks to a few months, those who show no favorable change, and those who will not tolerate the drug at all.

"3. By all the methods of control available and carefully analyzed figures, we can conclude that there is a shortening of the convalescent period or prolongation of life or both in the treated patients of group 1.

"4. There seems to be a real indication for the drug's use as a supportive treatment in collapse therapy when patients are not doing well and when there is a beginning spread to the other side, or when there is need to clear up a slight involvement of one side in preparation for collapse therapy on the other.

"5. Sanocrysin may be used to speed the convalescence of patients with favorable prognosis, but this is usually unnecessary.

"6. The drug may be added to the armamentarium of the tuberculosis specialist for use when other measures are unavailable, as well as for other 'reacting' types when the skill of the physician is able to direct a successful course.

"7. More experiment is warranted, so that indications, contraindications and more favorable types may be better established, in all ages, stages, complications, types of the disease, and in both sexes."

For many years Dr. Kime has advocated the administration of gold in the treatment of tuberculosis. He has had ample time to demonstrate the efficaciousness of his treatment to his fellow workers in the state of Iowa as well as in the nation, particularly those who limit themselves largely to the field of tuberculosis. He has frequently discussed papers on the treat-

ment of this disease but neither his method nor his results have gained much favor among physicians

The superintendent of one of the Iowa sanatoriums gave Dr Kime's "gold cure" an extensive trial approximately ten years ago with no favorable response on the part of any patient Dr Kime then preferred charges against the superintendent on the ground of lack of cooperation and the like However, the superintendent was vindicated and continued in his position

Unfortunately, in the past good results have been reported from special forms of treatment when modern methods of examination were not used and the evidence available would not always justify a diagnosis of clinical tuberculosis It is on such cases that most spectacular results have frequently been reported Therefore, in his publication in the Bombay *Medical Digest* it is hoped that all cases reported by Dr Kime are described with reference to diagnostic procedures so that no question can be raised by any physician as to the actual existence of clinical disease when his treatment was begun He should also have available to any physician who desires to review his material personally x-ray films of the chest in the beginning and periodically throughout the course of treatment, sputum reports from official laboratories, tuberculin tests, red cell sedimentation rates and every other bit of information that experts in tuberculosis would require in reaching a definite diagnosis Furthermore, he should make available to the profession unmistakable evidence that his patients have remained well over a sufficiently long period of time to convince the expert that remissions have not been mistaken for "cures"

CANCER NOT TRANSFERABLE FROM ANIMAL TO MAN

To the Editor —In a pamphlet entitled "Cancer as a Public Health Problem" George W Cox, a state health officer of Austin, Texas writes, as follows (p 4)

"At this time we have no facilities in the State Department of Health for the antemortem inspection of meat Last year one report shows 125 animals were rejected for slaughter because they were cancerous It is obvious that we may be eating a great deal of meat from cancerous animals The question as to the danger of eating such meat has never been investigated, but it may have a bearing on our increasing cancer incidence If it were possible for the State Department of Health to render this service, this danger along with others of similar magnitude would be controlled'

This paragraph appears to be endorsed by Dr J W E H Beck general chairman of the public health committee of the Texas department of the American Legion, in a circular letter dated March 14 The statement by Dr Cox and Dr Beck's letter lead me to ask Is there any danger of transmission of cancer in cattle to man? M D, Texas

ANSWER —There is no possibility and hence no danger of a transferring of cancer from cattle to human beings in the manner suggested by Dr Cox, because cancer is not transmissible even by transplantation from one mammalian species to another, e g from cattle to man Human cancer is not an infectious or contagious process like tuberculosis or actinomycosis The statement by Dr Cox should be corrected promptly because it may cause unfounded and unnecessary alarm with respect to an important source of human food

TONSILLECTOMY AND SYPHILIS

To the Editor —A man of 25 came to me on July 1, 1938, with chronically inflamed much hypertrophied tonsils His blood Wassermann reaction was found to be 3 plus The absence of a history or sign of a penile lesion caused me to believe that the tonsils were the point of origin of his syphilis Six intravenous treatments with 0 6 Gm of neoarsphenamine and twelve intramuscular treatments of sodium bismuth thioglycollate caused his blood to show 2 plus He is now in the second such course of treatment His tonsils have receded much in size but are still moderately red they are now about three times the normal size Would you advise tonsillectomy? If so when? M D Wisconsin

ANSWER —A diagnosis of syphilis should never be made on the basis of a single positive or, especially, partly positive serologic test for syphilis in the absence of history or physical signs There are too many opportunities for technical and biologic laboratory error to justify such a diagnosis If, in the patient in question, the diagnosis of syphilis hinges on one "3 +" complement fixation test followed after treatment by one "2 +" test, one cannot be certain that the patient actually has syphilis The serologic diagnosis should certainly be verified by check of the complement fixation test, by one or more reliable flocculation technics, and in one or more laboratories other than that which performed the original test

Whether the patient has syphilis or not, his tonsils, if chronically infected should be removed and operation may be performed immediately The only factors which influence surgical operations on syphilitic individuals are (*a*) the possible accidental infection of members of the operating team and (*b*) possible failure of wound healing because of the association of trauma with syphilitic lesions As to the former, the risk of infection to members of the operating team is almost wholly dependent on the duration of infection in the patient If he has early syphilis, i e of less than two years' standing, and if he has not been previously treated, there is some risk If, on the other hand, he has late syphilis, i e of more than five years' standing, whether or not he has been previously treated, there is little or no risk In either case and whether the patient's syphilitic infection is early or late, the administration of a course of an arsphenamine immediately prior to operation does away with the risk of infection (Parenthetically, it should be remarked that laryngologists who operate without gloves are particularly prone to the development of extragenital chancres, and no operation, even that of tonsillectomy, should be undertaken with bare hands under any circumstances, whether the patient is known to have syphilis or not)

The failure of wound healing is negligible without treatment and is entirely obviated by treatment before and after operation

In the patient in question, therefore, tonsillectomy may be performed immediately without risk to patient or operator, but in the meantime the diagnosis of syphilis in the patient should be verified

WIDAL TEST AND INTERCURRENT INFECTION

To the Editor —Following a three weeks siege of bronchial pneumonia caused by mixed infection with Streptococcus viridans predominating, a patient had an exhaustive bronchial cough for two weeks with temperature between 99 and 101 F Roentgenograms of the chest and examination of the sputum were negative but the Widal reaction was found positive in a dilution of 1 40 How long after immunization to typhoid will the Widal reaction be positive? Will prolonged low grade fever tend to cause a positive Widal reaction in a patient who has been immunized to typhoid several times, the last previous inoculation being three years ago? In this case an unhealed area in a bronchiectatic space could account for the fever but why the positive Widal reaction?

R A BUTLER M D, Safety Harbor, Fla

ANSWER —The Widal reaction may persist at low levels for years after an attack of typhoid or after vaccination with killed typhoid bacilli The agglutinin titer usually reaches its height, sometimes over 1 1,280, about two weeks after the last injection of vaccine, and then in the average case first diminishes rather rapidly for several months and at a slower rate thereafter It is not at all uncommon to find a low titer of 1 40 or 1 80 for several years During this time any intercurrent infection or vaccination against some other disease may cause a temporary increase in the titer which is sometimes referred to as an anamnesic reaction Such an occurrence is often confusing in making diagnoses

A Widal titer of 1 40 is not high enough to be of significance in making a diagnosis of typhoid In the case referred to it is highly probable that the atypical pneumonia or possible bronchiectasis was responsible for the presence of the Widal reaction

SOLUTIONS OF COMMON SEDATIVES

To the Editor —I should like full information concerning the preparation of sterile stock solutions of the common sedatives such as soluble phenobarbital and sodium amytal I have tried autoclaving such solutions, only to have the powder precipitate as a solid cake Why? Would autoclaving the dry powder and then dissolving it with aseptic technic solve the problem? Should the solution be passed through an Arnold sterilizer? What is the effect of heat on the solution? How long would such solutions keep in bottles in the wards? M D, District of Columbia

ANSWER —Barbituric acid and its many derivatives, which are used as sedatives and hypnotics, are not acids in the true sense of the word They do form soluble salts when combined with the alkali metals These salts are combinations of a weak "acid" and a strong base and as such are unstable when in solution When such solutions are subjected to boiling or to autoclaving or are allowed to stand for some time, hydrolysis takes place In the case mentioned, the hydrolysis liberates the free barbituric acid derivative which is insoluble This precipitates and forms the "cake"

A sterile solution could be prepared by heating the dry powder to about 125 C for some time (The United States Pharmacopeia directs that the powdered soluble phenobarbital is to be heated for six hours at 140 C in preparation for analysis) This could be dissolved in sterile water under aseptic technic No further treatment of the solution is necessary

The question as to how long such solutions would keep in bottles in the wards is difficult to answer The U S Pharmacopeia states that aqueous solutions of soluble barbiturates are alkaline in reaction and are unstable Several experiments with buffer solutions were tried, but the solutions either became cloudy or precipitated on standing One pharmaceutical house has a solution of a soluble barbiturate derivative on the market

This is dissolved in ethylene glycol and hence is not suitable for intravenous use. The fact that soluble barbiturate derivatives are marketed dry in ampules, to be put into solution with sterile water just before use, is evidence of the difficulties in preparing stable solutions of the soluble barbiturate derivatives.

BLEPHARITIS FROM MONILIA

To the Editor:—I have a patient who is afflicted with chronic blepharitis caused by *Monilia albicans*. His refractive error, practically negligible, has been corrected. Is there any specific treatment for blepharitic moniliasis? What is the prognosis? M.D., Connecticut.

ANSWER.—It would seem that blepharitis due to *Monilia albicans* is an exceedingly rare condition or at least that it is practically never recognized as such by ophthalmologists. No recommendations for treatment have been found in the literature. The logical treatment would seem to be the use of one of the drugs employed in treating monilia infections of the skin and mouth. Soaking the lids with a moist pack of 5 per cent sodium thiosulfate would be safe and might prove of value. The use of sodium thiosulfate in a 2 per cent ointment would offer another method of application. If there is also conjunctival infection, a 1 or 2 per cent solution of sodium thiosulfate would not damage the cornea. It is likely that the more commonly employed ointments, such as 2 per cent yellow mercuric oxide or 3 per cent ointment of ammoniated mercury might be of value as in other forms of blepharitis, provided the crusts are first removed with an applicator soaked in 3 per cent sodium bicarbonate.

INJURY TO RAMUS COMMUNICANS

To the Editor:—What effect has injury to the ramus communicans in the region of the twelfth dorsal and first lumbar vertebrae on the stomach? Would any chronic disturbance result? How? M.D., New York.

ANSWER.—It is doubtful that an injury to the ramus communicans in the region of the twelfth dorsal and first lumbar vertebrae would have any great effect on the stomach itself. The efferent innervation to the stomach is from the vagus and the white rami from the fifth to the twelfth thoracic nerves through the sympathetic trunk without interruption, to the celiac ganglion, celiac plexus to end in the musculature of the stomach. The location of the injury mentioned may result in changes in the large bowel and produce a chronic disturbance in this region by interrupting the synapse. This disturbance may be in the form of increased irritability of the bowel resulting from lack of inhibitory control.

LIVER EXTRACT FOR PSORIASIS

To the Editor:—A patient of mine suffering from psoriasis has called to my attention the recently published treatment for this disease by means of liver extract. I will appreciate any information you can give me on this question. The patient is a married woman of 25, apparently healthy in all other respects, has had psoriasis for about twelve years, and the only effective treatment so far has been ultraviolet exposures and the application of Dr. White's crude tar ointment. However, as soon as treatment is stopped, the lesions tend to recur.

STANLEY Z. WEISSHAUS, M.D., New York.

ANSWER.—Liver extract, like innumerable other injections, has been used with variable and indifferent results in the treatment of psoriasis. The use of crude coal tar ointment plus ultraviolet rays as described by Goeckerman (*Northwest. Med.* **24**:229 [May] 1925; *Arch. Dermat. & Syph.* **24**:446 [Sept.] 1931) is a good method of treatment when used persistently.

APPENDICAL ABSCESS

To the Editor:—I read on page 464 of THE JOURNAL for February 4, a query from Dr. Raymond H. McPherron of Chicago on the opening of an appendical abscess extraperitoneally. I felt that Dr. McPherron, in following up this idea, might be further interested in the principle of chemotaxis as applied to drainage in these cases, which principle has, I believe, been life saving in my hands and, I also believe, a subject much overlooked in the literature as well as in practice, in spite of the fact that it has been in use and attention has been called to it on numerous occasions by various authors. I submit here a few references on that subject, which I hope will be of value:

THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 14—AFTERNOON

Looking at Health Insurance Abroad

MR. J. GEORGE CROWNHEART, Madison, Wis.: As we discuss compulsory sickness insurance this afternoon we must keep uppermost in mind that, in the final analysis, we are talking about the care of individuals.

As I traveled the state of Wisconsin with a committee during the last eighteen months, going into some thirty-nine counties, sitting day after day with people from all walks of life and talking to them about their health and the health of their friends, I was impressed particularly with the fact that health problems frequently differed from county to county and even within counties. I would leave that as a background for our discussion.

The examination of sickness insurance abroad was undertaken in the sense of "Is the legislation in any one country, as it stands or with some modification, something that can be taken back and applied in Wisconsin to provide more people with a better sickness and health service?"

After completing the study, I was conscious of the fact that in England, Norway, Sweden, Denmark, Germany and France certain factors are common to the system regardless of whether the laws differ in their actual writing. I should like to discuss some of the elements which, one may fairly assume, are inherent to practice under compulsory sickness insurance.

First, the legislature establishes the premium. It says "This is the amount of money that we must raise for each person who is insured." Every pay check abroad, no matter how small, is taxed under compulsory sickness insurance. Persons under income limits that here would entitle them to receive service, without themselves contributing to it, abroad help the government to finance this service for themselves. Then the employer makes his contribution. Sometimes the government adds something, and sometimes it doesn't. But, regardless of that, in the initial legislation the premium is established. Now, I think that this would be all right were it not that physicians and medical science do not stand still. In the very time in which there has been compulsory sickness insurance abroad, the wide use of x-rays, first in diagnosis and then in therapeutics, has developed; insulin for diabetes, liver extract for pernicious anemia and other remedies have been discovered, and all of them initially cost more money. Socially they are cheap, but initially they require a greater outlay of funds than was anticipated at the time the legislation was passed. When small pay checks are being taxed, it is not politically expedient to increase that tax year after year. The administrator balances his books in the only way available to him by ignoring, for the great mass of his insured population, the steady advance of medical science.

Second, the fact that millions of dollars are involved does not mean that there is more money for each person who is ill. Millions of dollars were involved in Wisconsin in poor relief. An effort was made to find out why more work could not be done in the prevention of illness for people who were receiving this government service. It was discovered that, despite the fact that there were millions, there was only about $27 a month for each family of four for food, fuel, shelter, clothing, sickness care and health service.

The same principle holds in compulsory sickness insurance. Although millions are raised there is no more for each individual case of illness. Actually, there may be increasingly less from year to year. It is not known what the load is going to be, so most countries resort to the only thing possible

under the circumstances; they pin down the amount involved to make certain that their budget will be sufficient to cover the year, and they do it by making the physician the real insurer. They say, "Doctor, we now insure 50 per cent, 60 per cent, 80 per cent of the people in your community. Would you like to be part of the system?" Possibly he says yes. Then they say, as they do in England, "All right, we will pay you $2.25 a year for each person who selects you as his family physician at the time he is insured." The selection is generally not made at the time the illness occurs, on the basis of the individual illness, but at the time the person enters the insurance system, so the physician becomes the real insurer. He has accepted the stipulated amount for an unknown amount of service during the year.

If the physician were left alone at that point, he could probably figure out some way of jumping those handicaps, but he isn't. The government is interested in what the physician does because it has to pay for that, too.

In each system there is the little book, in which is set forth that which the physician may do, having in mind economical prescribing. If one talks to a physician who has gone out beyond the book, he may say "I did prescribe drugs not in the book, but my patient wasn't getting along well, and I read of something that had passed beyond the experimental stage, and I tried it, and my patient is back to work, but now I must explain to the regional medical officer about a patient he never saw, of whose family history he knows nothing, and tell him why I went out of the book and prescribed the more expensive procedure. You understand, of course, that the extra cost is subtracted from my next quarterly pay check."

Then something else happens. These systems do not administer themselves any more than an insurance company administers itself. In England one must admire the wonderfully high concept of civil service, far surpassing our own. Yet under such ideal conditions one finds that the administrative cost, after it is broken down, is 17 cents of the sickness dollar. In other countries it is as low as 10 per cent and 12 per cent but, when it is broken down, one is not altogether convinced that all which here would be regarded as administrative costs have been included.

One is told at the International Labor Office at Geneva that to collect the money, to check on the employer to make certain he has made the proper deductions, to check on the person who is sick in his home for more than a normal time, to check (in England) the 66,000,000 prescriptions a year to see that the physician has stayed within the little book and the pharmacist has priced the drugs right, to check on the treatment that is being given to the patient who requires more than a normal period of hospitalization, and to administer the whole scheme requires a group of employees varying from one for every fifty to one for every hundred persons insured.

Something else is even more important. In the National Hospital at Oslo, Norway, and I choose that one hospital merely because it comes to mind, I was tremendously impressed with the work that was being done under the handicaps of an old institution, handicaps which I think to physicians in my own state would seem almost insuperable. Yet down the street is a modern seven story office building with every type of modern business equipment, and here the system is administered. As the observer goes through this building, he cannot forget the building in which the sick are being cared for. He is impressed by the fact that under these systems the administration takes a dominant role.

As one spends hour after hour with the administrators of these systems, one is impressed constantly by a certain attitude and asks oneself why it prevails. Finally the answer comes from the lips of the administrator, and it is repeated time and time again: "Not all our people are sick at one time, only 2 or perhaps 4 per cent. All we know is that last year we hardly had money enough to get through the year. These sick people have been paying their contribution out of every week's pay check, and 2 per cent seems a lot when the pay check is small. They have been paying over a long period and they want the benefits. I have a 96 or a 98 per cent unknown demand. I don't know what it will be before the year is over. I have no other source of money. It must come from what I have raised, and this amount must last. We have a surplus, not in the vast amount that we think necessary, but at least a year's budget. So we must be watchful of our funds."

This attitude worries the observer, because the administrator, instead of assuming the role of guardian of the sick, becomes, as the years go by, more and more a trustee of money, and this conflicts with the concept of sickness care which prevails in our own country.

The regulations in Germany as well as in other countries contain a warning to the physician that, while in so-called private practice what he does is at the expense of the individual, under insurance practice it is at the expense of a third party.

An observer from the United States studying abroad finds creeping into the situation the hours of labor concept of legislation in Norway and the assignment of night calls exclusively to the young physician in Copenhagen, Denmark. He finds medicine in the role, whether it wishes to be there or not, of a salvager instead of the dynamic force, ever pushing back disease, that it is in the United States.

Then there is the overload on the physician. It is due in part to the fact that the amount that can be paid per person on the panel is so low that there must be a sufficient number on the panel to compensate and in part to the fact that, because the system is concerned even with pennies, the administrators would prefer that the physician limit his prescriptions in amount and that the patient go back three or four times, if need be, to have the prescription repeated instead of receiving a prescription for the full amount, in which case some of the medicine might be wasted. The overload does exist. The concept of sickness insurance to compile records on which further progress may be made in the prevention of disease is never realized. The concept of prevention in the sense of treating illness early is not found, because of the overload. It was not my observation that the physician abroad was any less humanitarian than the physician in my own state, but I was impressed that under rules and regulations he may find himself unable to do the thing that he is trained to do.

I spoke to an administrator in one country about the possibility of having periodic health examinations. I said "It seems to me, from my work on the governor's committee in Wisconsin, that over a period of years these would be the cheapest method, entirely aside from the humanitarian aspect in the care of the sick." "Well," he said, "that might be so. Undoubtedly it would over a long period, but how could we do it? We are swamped now by our demands. Are you suggesting that we should uncover more demands? Such a situation would be hopeless, from our point of view."

On my second visit to Oslo, it had just been determined to extend the sickness insurance downward from the age of 16 to 14. The medical association there had asked for the school medical record to be sent to the physician of choice for those who were then to be insured at the age of 14. It was explained that this couldn't be done because the school record was on a card that was one fourth inch too wide for the sickness insurance envelop but that, if the physician who wanted the record would write to the teacher of the school involved, a copy could be had at such times as he might wish it. Under these systems even the size of records become of commanding importance.

The effect extends beyond the insured. I quote from the report on British health services: "The nation needs sickness services, but a nation which regards them as a substitute for health services is going to find the confusion expensive in money and suffering. . . . It is no less necessary for those concerned with national health to examine the diseases of insurance schemes than it is to study heart disease and cancer."

There is a social purchase price for whatever economic security is involved in compulsory sickness insurance: 1. It is sold as a social service, but its operation as an insurance plan defeats this end. 2. It is sold in its preventive aspects, but its budget and operations reduce medical practice to the role of salvage. 3. Its beneficent intent is accepted as a guaranty of a quality of service that it is increasingly impossible to render. 4. To insure a balanced budget requires a control over the service that is rendered the sick, and that control is exercised in every country and not in accordance

Book Notices

Insulin: Its Chemistry and Physiology. By Hans F. Jensen, Ph.D., *Associate, Laboratory for Endocrine Research, The Johns Hopkins University, Baltimore.* Cloth. Price, $2. Pp. 252. New York: Commonwealth Fund; *London: Oxford University Press, 1938.*

In preparing this monograph on insulin, Dr. Jensen has performed a valuable service, particularly to those workers interested in diabetes and in investigations concerning carbohydrate metabolism. He has thoroughly reviewed the important literature up to 1938. To indicate the completeness of the work, one needs only to mention that, in the bibliography appended to the chapter on the physiologic action of insulin alone, 624 references are cited. Although the emphasis throughout is placed on the chemistry and physiologic action of insulin, sufficient reference to clinical application is made to make the work interesting and valuable for the clinician. Every doctor treating diabetic patients would profit by reading the introductory paragraph to chapter 6 on insulin substitutes. Among other statements the following excellent advice is given:

> An appreciable number of substances exist which will depress the blood sugar level in animals. More careful work has generally shown that, in spite of the superficial similarity in effect, the physiological action of these compounds is quite different from that exhibited by insulin itself. It is therefore obvious that every new insulin substitute should first be carefully studied in normal and depancreatized animals before its clinical trial on diabetic patients is attempted.

As a result of investigative work which is constantly in progress, our knowledge regarding carbohydrate metabolism, the action of insulin and related topics is always in a state of flux. Consequently it is desirable that from time to time new summaries be written. The monograph by Dr. Jensen can be thoroughly recommended.

Clinical Laboratory Methods and Diagnosis: A Textbook on Laboratory Procedures with Their Interpretation. By S. B. H. Gradwohl, M.D., Director of the Gradwohl Laboratories and Gradwohl School of Laboratory Technique, St. Louis, Mo. Second edition. Cloth. Price, $12.50. Pp. 1,607, with 536 illustrations including 44 color plates. St. Louis: C. V. Mosby Company, 1938.

This edition has been thoroughly revised and brought down to date. Each chapter contains enough of physiology and pathology for comprehension and interpretation of the tests that are mentioned. In the preface Gradwohl states that more than 100 pages have been added to the chapter on hematology, that complete data on the theories of blood development are given and that twenty-four color plates have been added. The views of several authorities are always included; footnote references to printed matter are abundant. The entire section on helminthology was written by Prof. Pedro Kouri of Havana, Cuba. Besides the customary chapters on each division of routine laboratory work, this book contains several interesting chapters on postmortem examinations, toxicologic technic and detection of crime by laboratory methods. This is valuable information for the rare occasions when even the smallest laboratory is called on to trace a questionable cause of illness or death. The manner of presentation is clear and interesting. The least doubt or confusion which may arise in the reader's mind is at once clarified by an example. Several approved tests for each determination are given. Technic is presented to the most minute detail. Preparation of reagents and equipment for each test are included with the test. The volume is somewhat bulky and rather expensive. Nevertheless it is an excellent textbook for technicians. It is particularly recommended for hospital laboratories and for physicians with private laboratories.

Untersuchungsmethoden für Arzneispezialitäten. Zusammengestellt von der Spezialitäten-Kommission des Internationalen Apothekerbundes. Second edition. Boards. Price, 3.50 florins; 5 marks. Pp. 148, with 10 illustrations. Leyde: Fédération internationale pharmaceutique; Amsterdam: Dekker en Nordemann N. V., 1938.

This edition is greatly improved. Besides the general technical methods, numerous specific determinations of chemical entities are given and clearly arranged in table form. Micro methods were used whenever they were found to be superior to the time and material consuming conservative standards. Many chemical assays of newer therapeutics are taken from New and Nonofficial Remedies. The committee members must be thanked for their enormous effort to place such a timely book of practical and precise analytic procedures in pharmaceutic chemistry again into the hands of international, private and government agencies connected with the enforcement of food, drug and cosmetic laws.

Maternity Care in a Rural Community, Pike County, Mississippi, 1931-1936. By Maxwell E. Lapham, M.D., Assistant Professor of Obstetrics, School of Medicine, the Tulane University of Louisiana, New Orleans. Paper. Price, 25 cents. Pp. 65. New York: Commonwealth Fund, 1938.

This is part of a stock taking of a public health program established in Pike County, Miss., in 1931 with the assistance of the Commonwealth Fund. Attention is focused on maternal mortality, which was 5.3 and 9.4 per thousand live births for white persons and Negroes respectively. "In regard to the Negro maternal deaths, it seems likely that the relatively poor economic conditions under which the patients lived caused a lowered resistance and greater tendency to develop some of the common conditions causing death, such as infection and toxemia." While, on the basis of an analysis which it is stated should be clearly understood as "in part speculative," it was determined that a certain percentage of the maternal deaths were due to "neglect and failure to obtain medical care on the part of the patient or midwife, and possibly ill advised interference on the part of the physician, . . . nearly half of the controllable deaths were due to neglect on the part of the patient or the patient's family." A suggested maternity program gives specific suggestions for the improvement of medical, midwife and nursing service.

Forelæsninger over klinisk Endokrinologi og beslægtede Emner. Første Række. *Af Herman Nielsen. [Lectures on* Clinical Endocrinology and Related Subjects. First Series.] Paper. Price, 12.50 kroner. Pp. 198, with 38 illustrations. Copenhagen: Levin & Munksgaard, 1938.

This monograph presents a series of clinical lectures on endocrinology and related conditions presented before university medical students. It comprises a clinical description of acromegaly, diabetes insipidus, adrenal disorders, Addison's disease, Cushing's syndrome, the climacteric, Paget's disease, scleroderma, Hand-Schüller-Christian disease, xanthomatosis and related disturbances in lipoid metabolism. The clinical descriptions are remarkably clear and usually from patients presenting the symptom complex under discussion. The illustrations are a distinct addition to the text. A familiarity with the published literature is equally evident. The chapter on xanthomatosis and the reticulo-endothelial system adds a new interest to the xanthoma problem. It emphasizes the principle that the xanthoma cell is a cell of the reticulo-endothelial system infiltrated with lipoids. The various manifestations of

xanthomatosis are regarded as expressions of disturbed lipoid and cholesterol metabolism. Of the many monographs that have appeared on clinical endocrinology, this is one of the most attractive and informative that have been published.

A Textbook of Histology: Functional Significance of Cells and Intercellular Substances. *By E. V. Cowdry, Professor of Cytology in the* School of Medicine, Washington University, St. Louis, Mo. Second edition. Cloth. Price, $7. Pp. 600, with 323 illustrations. Philadelphia: Lea & Febiger, 1938.

This edition has been enlarged by a hundred pages, and many new figures have been added. These should aid the student to understand more completely the sections he studies under the microscope. An introduction, partly historical, is intended to orient the students in their study. In various ways, such as directions for the examination of fresh tissues, the book has been improved for use as a laboratory guide. But these additions are not enough to make the study of histology easy for the average student. Freshman medical students probably need more explicit descriptions and guides than this textbook provides. This book should probably be supplemented in the laboratory by a small guide, such as Schaffer's. The great importance of the book, however, is that it heralds a new era in medical textbooks. It is a pioneer of the textbooks of the future. The author attempts (1) to present the subject of histology as a field in which progress is being made daily, (2) to awaken the student's intellectual curiosity to the problems which this subject presents, and (3) to initiate the student into that correlation of facts from many fields of investigation which will prove most useful to him in his later medical work. He carries out the first two aims by discussing both sides of controversial questions, with liberal extracts from the recent literature. The third aim is aided by tables, in which the significant anatomic and physiologic characteristics of tissues and organs are briefly enumerated. Whether the book will succeed in this threshold attempt, as well as impart the necessary histologic facts to the average medical student, is doubtful. It should be highly stimulating to teachers of the subject and to the more intellectually qualified medical students.

Nursing Care of Communicable Diseases: Prophylactic Technics for the Prevention and Control of Disease. By Mary Elizabeth Pillsbury, R.N., M.A. With a chapter on Fungous Diseases. By Grace Maguire Swanner, M.D. And a Brief Picture of Public Health Nursing. By Mary E. Edgecomb, R.N., Science Adviser: Jean Broadhurst, Ph.D., Professor of Bacteriology, Teachers College, Columbia University, New York City. Fifth edition. Cloth. Price, $3. Pp. 603, with 137 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1938.

There is assembled in this edition an unusual amount of valuable information. The scope of the subject is broad; the material is concise and well arranged. Part I, which comprises approximately one third of the volume, contains chapters every nurse should read. The importance and technic of medical asepsis are emphasized. Cause, mode of transmission and resistance to disease are discussed. The functions of the nurse in disease control and measures for public health control are outlined. Prophylactic technic for the nurse and methods for establishing immunity against various infections are set forth. Part II relates to a large number of the better known communicable diseases and gives specific instructions regarding the nursing care of each. In part III is found miscellaneous information, which includes a historical review of the care of communicable diseases. The value of the book is enhanced by illustrations and charts. It should be of great assistance not only to the nurse in training but to the graduate and to the medical student as well. For one who contemplates entering the field of public health this treatise will prove to be a splendid acquisition.

La amibiasis en Chile. Por el Dr. Amador Neghme Rodriguez, jefe de laboratorio de la cátedra de parasitologia, Santiago. Paper. Pp. 48, with illustrations. Santiago: Imp. el imparcial, 1938.

In this monograph one will find a brief summary of the most commonly known literature on amebiasis and the results of the author's observations on amebiasis in Chile. After more than two years of study on cultural methods and after devising a new modification, he has concluded that culturing Endamoeba is more of scientific interest than of practical use. After discussing briefly some well known facts concerning the epidemiology of amebiasis, he gives the results of studies made in Chile during the years 1934 to 1937 inclusive. Two hundred and eighty-five patients were examined in the laboratory of parasitology of the school of biology and medical sciences. Forty-three (50.08 per cent) harbored Endamoeba histolytica (the author prefers the term E. dysenteriae). In the Hospital del Salvador there were 827 patients examined in 1937 and 11.36 per cent were infected with E. histolytica, while in other hospitals the rates of infection varied from 7.67 per cent to 11.26 per cent. Among 790 soldiers examined the rates varied from 2.7 to 10.12 per cent. The author has infected cats with cultures of amebas by rectal inoculation as well as by inoculation directly into the ileum, both before and after splenectomy.

Virus Diseases and Viruses. By Sir Patrick P. Laidlaw, M.A., B.Ch., F.R.C.P. The Rede Lecture 1938. Boards. Price, 90 cents; 2s. 6d. Pp. 52. New York: Macmillan Company, Cambridge: University Press, 1938.

This brief "lecture" on virus diseases and viruses represents some of the views of one of the most distinguished contributors in the field. Perhaps its most important aspect is the author's theory on the origin of viruses, which is entitled to receive the careful attention of workers in the field.

Have You Had Your Vitamins? By Harry N. Holmes, Ph.D. Cloth. Price, $1. Pp. 60, with 3 illustrations. New York & Toronto: Farrar & Rinehart, Inc., 1938.

Written by a distinguished professor of chemistry at Oberlin College, this little book is intended for the intelligent housewife and "others interested in vitamin therapy." Those persons who feed vitamin pills to their families will find plenty of support in the "conservative advice" of the author. With the unfortunate publicity that shotgun vitamin mixtures are receiving it would seem that the advice in this book is superfluous.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Atrophy of Optic Nerve Attributed to Exposure to Heat and Glare of Furnace.—For about ten years the workman in this case had been employed by the defendant petroleum company to fire furnaces and boilers. On May 28, in adjusting a valve on a particular boiler, he was forced to look at the flame for five minutes to adjust the flame to a target in the boiler, a task he had performed many times before. Thereafter he became blind and instituted suit under the workmen's compensation act of Louisiana. The trial court gave judgment against the workman and he appealed to the court of appeal of Louisiana, first circuit.

The evidence before the trial court showed that the workman had had syphilis for several years before the incident to which he attributed the loss of his sight and that his vision had been impaired. A physician who had examined the workman about fourteen months after the alleged industrial accident testified that he found him suffering from an advanced stage of neurosyphilis and that the optic nerve was atrophied. There was medical evidence to the effect that syphilis is the principal cause of atrophy of the optic nerve, although it is not the sole cause. Medical experts testified that heat and glare, without some severe burns around the eyes, would not cause atrophy of the optic nerve and that exposure to heat and glare in firing a boiler would not affect or aggravate a syphilitic condition so far as it relates to the optic nerve. If, said the court of appeal, the glare and heat from the boiler or furnace served to aggravate or hasten the atrophy of the optic nerve because of the weakened condition of the nerve brought on by syphilis, and if this heat and glare on that particular day was unusual and out of the ordinary routine of the day's work, it could be said that the heat and glare from the boilers had a causal connection with the blindness, and the workman would be entitled to compensation. *There was, however, no evidence to this effect.* On

the contrary, the evidence showed that the atrophy of the optic nerve and the resulting blindness were caused by syphilis, not by the exposure of the workman to the heat and glare of the boilers. The workman therefore failed to show that his disability was caused or superinduced by an accident or injury in the course of his employment. The judgment in favor of the employer was accordingly affirmed.—*Laughlin v. Magnolia Petroleum Co. (La.), 182 So. 178.*

Insanity: Constitutionality of Statute Authorizing Court to Appoint Commission to Determine Sanity.—Noelke was prosecuted for the murder of his wife and infant daughter. He entered pleas of not guilty and of insanity. In accordance with an Indiana statute, which provides that when an insanity defense is pleaded the court shall appoint two or three competent disinterested physicians to examine the defendant and testify at the trial, the trial court appointed three physicians to examine Noelke and testify as to his sanity. At the trial the three physicians were permitted to testify, over Noelke's objection, that, from their examinations and observations, they were of the opinion that he was of sound mind. From a conviction of murder in the first degree, Noelke appealed to the Supreme Court of Indiana.

Noelke contended that the statute was unconstitutional in that the effect of the testimony of these physicians as to his sanity, based on their observation and examination of him, was to compel him to testify against himself contrary to the constitution of Indiana, which provides: "No person, in any criminal prosecution, shall be compelled to testify against himself." The Supreme Court, however, cited several court decisions holding that testimony by a medical expert as to sanity, based on his observation and examination, is competent and does not amount to compelling an accused to give evidence against himself. Witnesses appointed by the court to examine and observe a person who is accused of a crime and who has filed a plea of insanity affords the court and jury testimony as free from influence and prejudice as is humanly possible to obtain. Such examinations by experts must be confined within constitutional limitations. In the judgment of the court, no constitutional right of Noelke had been violated and the judgment of conviction was affirmed.—*Noelke v. State (Ind.), 15 N. E. (2d) 950.*

COMING MEETINGS

American Medical Association, St. Louis, May 15-19. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

Alabama, Medical Association of the State of, Montgomery, April 18-20. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.

American Academy of Tuberculosis Physicians, St. Louis, May 13-14. Dr. Arnold Minnig, 638 Metropolitan Bldg., Denver, Secretary.

American Association for the Study of Goiter, Cincinnati, May 22-24. Dr. W. Blair Mosser, 133 Biddle St., Kane, Pa., Secretary.

American Association for Traumatic Surgery, Hot Springs, Va., May 8-9. Dr. Ralph G. Carothers, 409 Broadway, Cincinnati, Secretary.

American Association of Genito-Urinary Surgeons, Williamsburg, Va., May 24-26. Dr. Charles C. Higgins, 2050 East 93d St., Cleveland, Secretary.

American Association of Industrial Physicians and Surgeons, Cleveland, June 5-8. Dr. V. S. Cheney, Armour and Company, Union Stock Yards, Chicago, Secretary.

American Association of the History of Medicine, Atlantic City, N. J., April 30-May 1. Dr. Henry E. Sigerist, 1900 Monument St., Baltimore, Secretary.

American Association on Mental Deficiency, Chicago, May 3-6. Dr. E. Arthur Whitney, Washington Road, Elwyn, Pa., Secretary.

American Bronchoscopic Society, Rye, N. Y., May 26. Dr. Lyman [illegible] Ave., Boston, Secretary.

[illegible]ssociation, Montebello, Canada, May 31-June 3. University of Pennsylvania Medical Laboratories, Philadelphia, Secretary.

American Gastro-Enterological Association, Atlantic City, N. J., May 1-2. Dr. Russell S. Boles, 1901 Walnut St., Philadelphia, Secretary.

American Gynecological Society, White Sulphur Springs, W. Va., May 22-24. Dr. Richard W. TeLinde, 11 East Chase St., Baltimore, Secretary.

American Heart Association, St. Louis, May 12-13. Dr. Howard B. Sprague, 50 West 50th St., New York, Secretary.

American Laryngological Association, Rye, N. Y., May 24-26. Dr. James A. Babbitt, 1912 Spruce St., Philadelphia, Secretary.

American Laryngological, Rhinological and Otological Society, Chicago, May 10-11. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Medico-Legal Association, Chicago, May 12-13. Dr. Michel Pijoan, 124 Commonwealth Ave., Boston, Secretary.

American Neurological Association, Atlantic City, N. J., June 5-7. Dr. Henry A. Riley, 117 East 72d St., New York, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Eugene M. Blake, 303 Whitney Ave., New Haven, Conn., Secretary.

American Orthopedic Association, Buffalo, N. Y., June 5-8. Dr. Ralph K. Ghormley, 110 Second Ave. S.W., Rochester, Minn., Secretary.

American Otological Society, New York, May 22-23. Dr. Thomas J. Harris, 104 East 40th St., New York, Secretary.

American Pediatric Society, Sky Top, Pa., Apr. 27-29. Dr. Hugh McCulloch, 325 North Euclid Ave., St. Louis, Secretary.

American Physiological Society, Toronto, Canada, Apr. 26-29. Dr. A. C. Ivy, 303 East Chicago Ave., Chicago, Secretary.

American Psychiatric Association, Chicago, May 8-12. Dr. Arthur H. Ruggles, Butler Hospital, Providence, R. I., Secretary.

American Rheumatism Association, St. Louis, May 15. Dr. Loring T. Swaim, 372 Marlborough St., Boston, Secretary.

American Radium Society, St. Louis, May 15-16. Dr. Frederick W. O'Brien, 465 Beacon St., Boston, Secretary.

American Society for Clinical Investigation, Atlantic City, N. J., May 1. Dr. Isaac Starr, University of Pennsylvania Hospital, Philadelphia, Secretary.

American Society for Experimental Pathology, Toronto, Canada, April 26-29. Dr. Paul R. Cannon, Dept. of Pathology, University of Chicago, Chicago, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Toronto, Canada, Apr. 26-29. Dr. G. Philip Grabfield, 319 Longwood Ave., Boston, Secretary.

American Society for the Study of Allergy, St. Louis, May 15-16. Dr. J. Harvey Black, 1405 Medical Arts Bldg., Dallas, Texas, Secretary.

American Society of Biological Chemists, Toronto, Canada, Apr. 26-29. Dr. C. G. King, Univ. of Pittsburgh, Dept. of Chemistry, Pittsburgh, Secretary.

American Society of Clinical Pathologists, St. Louis, May 12-14. Dr. Alfred S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Surgical Association, Hot Springs, Va., May 11-13. Dr. Charles G. Mixter, 319 Longwood Ave., Boston, Secretary.

American Therapeutic Society, St. Louis, May 12-13. Dr. Joseph F. Elward, 1726 Eye St. N.W., Washington, D. C., Secretary.

American Urological Association, White Sulphur Springs, W. Va., May 29-June 1. Dr. Clyde L. Deming, 789 Howard Ave., New Haven, Conn., Secretary.

Arkansas Medical Society, Hot Springs National Park, May 8-10. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Associated Anesthetists of the United States and Canada, St. Louis, May 15. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary General.

Association for the Study of Internal Secretions, St. Louis, May 13-14. Dr. E. Kost Shelton, 921 Westwood Blvd., Los Angeles, Secretary.

Association of American Physicians, Atlantic City, N. J., May 2-3. Dr. Hugh J. Morgan, Vanderbilt University Hospital, Nashville, Tenn., Secretary.

Association of Military Surgeons of the United States, Washington, D. C., May 8-10. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.

California Medical Association, Del Monte, May 1-4. Dr. George H. Kress, 450 Sutter St., San Francisco, Secretary.

Connecticut State Medical Society, New Haven, May 25-26. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

District of Columbia, Medical Society of the, Washington, April 25-27. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Executive Secretary.

Federation of American Societies for Experimental Biology, Toronto, Canada, Apr. 26-29. Dr. D. R. Hooker, 19 West Chase St., Baltimore, Secretary.

Florida Medical Association, Daytona Beach, May 1-3. Dr. Shaler Richardson, 111 W. Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Atlanta, Apr. 25-28. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.

Illinois State Medical Society, Rockford, May 2-4. Dr. H. M. Camp, 224 S. Main St., Monmouth, Secretary.

Iowa State Medical Society, Des Moines, Apr. 25-27. Dr. Robert L. Parker, 3510 Sixth Ave., Des Moines, Secretary.

Kansas Medical Society, Topeka, May 1-4. Mr. C. G. Munns, 112 W. 6th St., Topeka, Executive Secretary.

Louisiana State Medical Society, Alexandria, Apr. 24-26. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, Apr. 25-26. Dr. Walter Dent Wise, 1211 Cathedral St., Baltimore, Secretary.

Massachusetts Medical Society, Worcester, June 6-8. Dr. Alexander S. Begg, 8 Fenway, Boston, Secretary.

Minnesota State Medical Association, Minneapolis, May 31-June 2. Dr. B. B. Souster, 11 West Summit Ave., St. Paul, Secretary.

Mississippi State Medical Association, Gulfport, May 9-11. Dr. T. M. Dye, McWilliams Bldg., Clarksdale, Secretary.

National Gastroenterological Association, New York, June 1-2. Dr. G. Randolph Manning, 1819 Broadway, New York, Secretary.

Nebraska State Medical Association, Grand Island, May 2-4. Dr. R. B. Adams, 414 Federal Securities Bldg., Lincoln, Secretary.

New Hampshire Medical Society, Manchester, June 8-9. Dr. Carleton R. Metcalf, 5 South State St., Concord, Secretary.

New Jersey, Medical Society of, Atlantic City, June 6-8. Dr. Alfred Stahl, 55 Lincoln Park, Newark, Secretary.

New Mexico Medical Society, Gallup, May 11-13. Dr. L. B. Cohenour, 219 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Syracuse, April 24-27. Dr. Peter Irving, 2 East 103d St., New York, Secretary.

New York State Association of Public Health Laboratories, Valhalla, May 8. Miss Mary B. Kirkbride, New Scotland Ave., Albany, Secretary.

North Carolina, Medical Society of the State of, Cruise to Bermuda, May 9-14. Dr. T. W. M. Long, Roanoke Rapids, Secretary.

North Dakota State Medical Association, Fargo, May 8-10. Dr. Albert W. Skelsey, 20½ North Broadway, Fargo, Secretary.

Ohio State Medical Association, Toledo, May 3-4. Mr. C. S. Nelson, 79 E. State St., Columbus, Executive Secretary.

Oklahoma State Medical Association, Oklahoma City, May 1-3. Dr. L. S. Willour, Third and Seminole, McAlester, Secretary.

Rhode Island Medical Society, Providence, June 7-8. Dr. Guy W. Wells, 124 Waterman St., Providence, Secretary.

Society for the Study of Asthma and Allied Conditions, Atlantic City, N. J., Apr. 29. Dr. W. C. Spain, 116 E. 53d St., New York, Secretary.

Society of Surgeons of New Jersey, Elizabeth, May 31. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

South Dakota State Medical Association, Aberdeen, Apr. 24-26. Dr. Clarence E. Sherwood, Madison, Secretary.

Texas, State Medical Association of, San Antonio, May 8-11. Dr. Holman Taylor, 1404 West El Paso St., Fort Worth, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore

125: 205-414 (Feb.) 1939. Partial Index

Role of the Thyroid in the Carbohydrate Disturbance Which Follows Hypophysectomy. S. Soskin, R. Levine and R. E. Heller, Chicago.—p. 220.

Decreased Resistance to Hypoglycemia on Successive Days of Administration of Insulin. W. C. Corwin, Rochester, Minn.—p. 227.

Intramyocardial Pressure and Its Relation to Aortic Blood Pressure. J. R. Johnson and J. R. Di Palma, Brooklyn.—p. 234.

Thyroid Stimulation by Cold, Including the Effect of Changes in Body Temperature on Basal Metabolism. G. C. Ring, Boston.—p. 244.

Effects of Preganglionic Denervation on the Superior Cervical Ganglion. A. Rosenblueth and W. B. Cannon, Boston.—p. 276.

Some Chemical and Physiologic Properties of the Gonadotropic Antagonist. C. A. Bunde and A. A. Hellbaum, Oklahoma City.—p. 290.

Plasma Prothrombin Levels in Various Vertebrates. E. D. Warner, K. M. Brinkhous and H. P. Smith, Iowa City.—p. 296.

Vasoconstriction in the Hand from a Deep Inspiration. M. G. Mulinos and I. Shulman, New York.—p. 310.

Acute Riboflavin Deficiency in the Dog. H. R. Street and G. R. Cowgill, New Haven, Conn.—p. 323.

Reproductive Performance of Albino Rats with Previous Vitamin A Depletion Histories. L. G. Browman.—p. 335.

Function of Muscles in Locomotion. H. Elftman, New York.—p. 357.

Gonadotropic Content of Hypophysis Throughout the Life Cycle of the Normal Female Rat. H. D. Lauson, June B. Golden and E. L. Sevringhaus, Madison, Wis.—p. 396.

Physiologic Action of Natural and Artificial Radioactivity. J. G. Hamilton and G. A. Alles, Berkeley, Calif., and San Francisco.—p. 410.

American Journal of Public Health, New York

29: 1-94 (Jan.) 1939

The National Health Conference and the Future of Public Health. A. J. Altmeyer, Washington, D. C.—p. 1.

Attitude of the American Medical Association Toward the National Health Program. I. Abell, Louisville.—p. 11.

The Public Health Aspects of Medical Care: From the Standpoint of Public Health. C.-E. A. Winslow, New Haven, Conn.—p. 16.

*Questionable Value of Skin Testing as a Means of Establishing an Epidemiologic Index of Tuberculous Infection. L. L. Lumsden, W. P. Dearing and R. A. Brown, New Orleans.—p. 25.

Preparation and Analysis of Diagnostic Antipneumococcus Serum. H. Welch, E. K. Borman and F. L. Mickle, Hartford, Conn.—p. 35.

Pneumococcus Diagnostic Serum. E. S. Robinson, Boston.—p. 43.

Is the Private Health Agency on the Way Out? B. Marquette, Cincinnati.—p. 46.

Is There a Place for the Voluntary Health Agency in View of the New Public Health Activities of the Federal Government? H. E. Kleinschmidt, New York.—p. 49.

The State Public Health Nursing Unit and Its Relation to Special Services. Jane D. Nicholson, Washington, D. C.—p. 55.

Laboratory Administration as Regards Syphilis Serology. J. F. Mahoney and Margaret R. Harrison, Stapleton, Staten Island, N. Y.—p. 61.

Epidemiologic Index of Tuberculosis.—Lumsden and his associates question the value of cutaneous testing with tuberculin preparations based on an analysis of about 12,000 persons who were given tuberculin cutaneous tests. A purified protein derivative of tuberculin from two firms was used. School children were the first to be studied. Of 177 (4,400 children tested in two counties) white children ranging in age from 6 to 19 years at the first school tested only 14.7 per cent showed positive reactions. This percentage was surprisingly low in view of the much higher percentage of positive reactions reported by others. The authors' results were strikingly variable with different tuberculins which indicate to them that different preparations of tuberculin now used extensively by health agencies vary greatly in potency and/or specificity and signify that the percentage of positive reactors to cutaneous tests among school children, and inferentially among other general population groups, depends largely on the particular preparation of tuberculin used in making the tests. Satisfactory epidemiologic measurements cannot be made with such varying "yardsticks." The authors state that their observations appear to cast doubt not only on the validity of recorded and exploited rates of subclinical tuberculous infection which have been established in different communities for the same period or in one community for different periods of time solely on a basis of results of cutaneous testing with different preparations of tuberculin but also on the significance of the observations in two or more communities tested at the same time, method, dosage and preparation of tuberculin. The results of tuberculin testing and those of x-ray study of the chests were far apart as epidemiologic indicators.

American Journal of Tropical Medicine, Baltimore

19: 1-96 (Jan.) 1939

Malaria: Retrospect and Prospect. M. F. Boyd, Tallahassee, Fla.—p. 1.

Comments on Some of the Unsolved Problems of Research and Disease Control in the Tropics. J. F. Siler, Washington, D. C.—p. 7.

Failure of Aedes Aegypti to Transmit Yellow Fever Cultured Virus (17D). L. Whitman, Rio de Janeiro, Brazil, South America.—p. 19.

Lactogenic Hormone: Severe Reactions from Its Use. A. A. Werner, St. Louis.—p. 119.

Sex Sterols in Menometrorrhagia.—Hamblen discusses a form of treatment which employs the cyclic administration of estrogen and progesterone or of progesterone alone. Observations were made on twelve patients with functional uterine bleeding. They received a total of forty-six series of treatments. During the period of treatments regular cyclic bleeding occurred and when the injections were discontinued none of the patients experienced a return of excessive bleeding. Some evidence is presented that these cyclic treatments alter the pathologic aberrations of the pituitary-ovarian-endometrial system, thereby overcoming theoretical ovarian and endometrial refractivity and the associated alterations in the gonadotropic effects of the pituitary. The method of treatment has been essentially as follows: A remission from bleeding is induced, if necessary, by estrogenic therapy or curettage. One week later, injections of estrogen in daily doses of from 10,000 to 20,000 international units are begun and continued for fourteen consecutive days. Progesterone is then given daily in doses of 5 international units for the next seven days. At the conclusion of this treatment, and frequently before it is finished, bleeding occurs. This has been found, as a rule, to be comparable in amount and in duration to that experienced by healthy women. No treatments are given during the week set aside for bleeding. Injections of progesterone are discontinued when bleeding begins. If these are continued, experience has been that excessive and prolonged bleeding often results. One week after the onset of bleeding, treatments are repeated in the same fashion. If bleeding lasts longer than seven days, injections of estrogens cause it to stop. Series of this combined therapy are given for from three to six months.

Sulfanilamide in Treatment of Acute Gonorrhea in the Male. H. A. Bogaev, E. T. Litt and D. M. Davis, Philadelphia.—p 75.
Growth of Neisseria Gonorrhoeae on the Chorio-Allantoic Membrane of Chick Embryo. Justina H. Hill and Anne C. Pitts, Baltimore.—p. 81.
Possible Anatomic Relations Between Pituitary Body and Prostate Gland: I. Normal Pituitary Body. H. M. Jones, Rochester, Minn.—p. 84.
Self Induction Analgesia with Nitrous Oxide for Urologic Examinations and Minor Procedures. H. H. Young, Baltimore.—p. 95.

Pathologic Changes in Fused Kidney.—Shoemaker and Braasch state that at the Mayo Clinic during the years from 1905 to April 1938 thirty-five instances of fused kidney were observed in the course of postmortem examinations. The incidence was 1:385 necropsies, which is higher than that of most authors (1:700). The advent of intravenous urography, however, has increased the incidence to about 1:200 persons (Gutierrez). In twenty-four cases the ureters, pelves and calices were normal except for their position in relation to the renal parenchyma. In eleven cases there was some degree of dilatation of the ureters, pelves or calices. In five of these eleven cases the dilatation was limited to the calices and pelvis and may be considered the result of the anomaly. There were eight cases of hypertrophy of the prostate gland and one of stricture of the urethra. In six of these there also was some dilatation of the upper part of the urinary tract. In four the dilatation was probably secondary to the obstructing lesion in the lower part of the urinary tract (prostatic hypertrophy in three cases and stricture of the urethra in one). Dilatation was secondary to a vesicocolonic fistula in another case. Pyelograms were made in only three cases. In two the possibility of fused kidney was suggested by pyelography but in another the diagnosis could not be made by this means. Sections were examined microscopically in twenty-one cases. Ten of these specimens appeared grossly normal. There were three cases of pyelonephritis (two with abscess formation). The remaining specimens were normal microscopically or pathologic changes were observed which would be found as often in anomalous as in normal kidneys. Coexistent congenital anomalies were present in eleven cases.

Chemotherapy in Meningitis.—Appelbaum believes that future progress in the treatment of meningitis secondary to infections of the ears and sinuses will depend mainly on the development of a more effective chemotherapeutic agent, capable perhaps of attacking the primary foci of infection. He has begun to use sulfapyridine in pneumococcic meningitis and hopes to report on it at some future date. The use of sulfanilamide in cases of meningitis due to the hemolytic streptococcus has yielded marvelous results. The prompt and complete eradication of the primary foci of infection is of particular importance in the forms of meningitis under consideration. Sulfanilamide therapy marks an important advance. By means of this drug and its derivatives one can now treat successfully many of the otherwise almost uniformly fatal infections.

*Effects of Basketball on Junior High School Boys. A. B. Bowyer and N. S. Anderson, Buckhannon.—p. 89.

Effects of Basketball on Junior High School Boys.—Bowyer and Anderson show that with the new ten second rule the game of basketball is extremely strenuous on junior high school boys from 12 to 16 years of age. To determine whether there is any harmful effect on the hearts of boys of this age playing basketball they have checked the blood pressure and heart rates of boys before and after each basketball game. They also made a preseason and postseason test. The mean or average of the preseason systolic pressure was 108 plus or minus 2.78 and the mean of the postseason pressure was 111.6 plus or minus 2.95. The true difference between the means was 3.6, which was a gain in systolic pressure. The critical ratio was 0.89, which indicates that the mean of the preseason and postseason test is not statistically significant. The authors, therefore, drew the conclusion from their studies that basketball under the old rules did not have any harmful effects on junior high school boys. With their conclusions of 1936-1937 showing no harmful effects, they continued the study under the new rules. One of the most interesting comparisons is made between a hard game and an easy one. In the easy game sixteen boys played at some time or other. There was not a boy on the squad who played the whole game. The heart rates taken twenty minutes after the easy game show that in all the boys but one it had returned to normal, and in this one it was only a fraction higher. The results of a hard game show that the blood pressure of some of the boys goes down, while the pressure of others is increased by exercise. When the blood pressure goes below normal, it indicates a period of staleness or acute fatigue. The boys who did not play the full game would return to normal very quickly after the game. From this the authors decided that a full game of basketball under the new rule was too strenuous on junior high school boys. Their conclusion is substantiated by S. J. Morris of the Health Unit of West Virginia University. The mean pulse rate of the four hardest games of the authors' squad was found to be 146 five minutes after the game. After twenty minutes the heart rate was still 115. The preseason and postseason tests were taken under ideal conditions without the emotional strain of a game. The postseason test shows that the boys' heart rates are higher while their blood pressures are lower. The high heart rates and low blood pressure indicate periods of fatigue that naturally place a strain on the circulatory system. The authors are unable to say with any final degree of authority, but the probabilities are that if this type of strenuous exercise is practiced year after year during the adolescent period it will produce a weakened circulatory system, which may develop into a handicap in later life. They conclude that basketball as played under the present rules is too strenuous for junior high school boys unless several boys, given each at least one quarter of the four to rest in, participate in one game.

Chronic Fluorine Poisoning.—Moller points out that the principal x-ray sign of fluorine poisoning is the changes in the bones. In the cases of severest poisoning the bones, especially the spongy bones, are enormously changed, both in structure and in outline. What first impresses one in looking at roentgenograms of the vertebral column and the pelvis is the almost complete disappearance of normal bony structure, which has been replaced by an almost absolute milky white opacity. The isolated trabeculae appear thick, dense and of a woolly indistinctness. The outlines of the vertebrae too are absolutely lacking in sharpness. The transverse processes are wide, thick and covered with small excrescences, and the spinous processes shine through as a dense, irregular band. This is because, in severe poisoning, the ligaments and fibrocartilaginous attachments also are the seat of extensive calcification. The ligaments on the anterior and lateral aspects of the vertebral bodies form, when calcified, actual bridges between those bodies, and in some cases the picture resulting from the calcifications resembles that of ankylopoietic spondylitis. The posterior ends of the ribs are covered along the edges with large, irregular excrescences resembling hoarfrost needles. In the extremities the compact layers of bone are greatly thickened and the marrow cavities narrowed. The normal cristae are prominent, and at the points of attachment of the large muscles there are large irregular calcifications of the fibrocartilages. The small bones of the hands and feet present the same appearance, but the density is not so great. In the most severe poisoning changes in the cranium also occur. The roentgenologist should be acquainted with the curious osseous changes resulting from such poisoning.

X-Ray Manifestations of Bilharziasis.—The extent of bilharzial infestation can be determined roentgenologically. Ragheb states that bilharziasis exhibits itself on the roentgenogram in two forms: 1. The deposition of ova in the submucosa is followed by ulceration and subsequent calcareous depositions. 2. The deposition of ova is followed by the formation of papillomas; the papillomas, in their turn, may ulcerate or become calcified and then will give the appearance of a calculus. The first form is predominant in the bladder, ureters and seminal vesicles. The second form is usual in the intestine, kidney and pelvis of the kidney.

*Painful Vertebral Osteoporoses. P. P. Ravault, J. Graber-Duvernay and G. Léger.—p. 69.
Preclinical Period. P. Delore.—p. 87.

Painful Vertebral Osteoporoses.—Attention has been called to a curious syndrome characterized anatomically by a striking elective decalcification of the vertebral bodies, likely to produce gross morphologic modifications of the vertebral column; clinically, pain occupies a predominant place. This painful vertebral syndrome of osteoporotic origin must be differentiated from other painful disorders of the vertebral column. It responds to a therapy which in certain cases produces extremely favorable results. Ravault and his associates agree with Decourt that these cases of painful vertebral osteoporoses must be considered as localized forms of osteomalacia. Then they describe the clinical histories of eight personally observed cases and in the subsequent discussion they take up the subjective, objective, roentgenologic and humoral signs of the disorder. After discussing the etiology and pathogenesis they give their attention to the diagnosis and particularly the *differentiation from such disorders as Pott's disease, vertebral* cancer, Kümmell-Verneuil's disease, vertebral rheumatism and senile kyphosis. The therapy of painful vertebral osteoporoses has two chief aims: recalcification and counteracting of the pains. The first object is accomplished by injectable calcium preparations, by vitamins D and A and by the application of ultraviolet rays or heliotherapy. If success is obtained, the pains gradually subside. However, this successful outcome of the treatment is far from being constant; there are some cases which are not improved. A suitable diet may be of assistance in the treatment. The authors recommend especially milk, egg yolks, potatoes, cabbage, peas and fruits. The diet should be rich in vitamins and should stimulate the appetite. In counteracting the pains, the remedies for nervous disorders such as acetylsalicylic acid and antipyrine are not efficient, since their effect is always transitory. The same can be said about the treatment with diathermy and with short waves. Roentgen therapy was found to produce exacerbation of the pains in one instance. On the other hand, the authors found the intradermal injection of histamine effective in a patient who was not improved by the recalcification treatment. One patient was improved only by a series of shocks induced with a sulfur preparation. Finally, orthopedic measures may prove helpful.

Metastatic Osseous Suppurations in Adults.—Peycelon points out that acute infectious processes of the skeleton which are truly primary are relatively rare in adults. Many of those which appear in adults are recurrences of osteomyelitic processes of adolescence which had either been forgotten by the patient or had not been recognized at that age. The majority of acute osteomyelitic processes of adults appear as metastatic suppurations. The port of entry can nearly always be found by reference to recent clinical manifestations such as an acute pulmonary process, angina and cutaneous lesions. The localization of the metastatic osseous suppuration of adults presents some unusual aspects: one is that its site of predilection is the long bones, particularly the femur. Nevertheless the flat bones are not exempt, for the author observed it in the iliac crest and in the acetabulum. The most curious aspect, however, is the mediodiaphysial localization of the infectious osseous focus in adults, because this diaphysial site contrasts with the juxta-epiphysial topography of such lesions in adolescents. As regards the anatomoclinical aspects, the author differentiates three forms: (1) the panosteitis, which involves

all parts of the bone from the periosteum to the medullary cavity, (2) the cortical osteitis, which is more superficial, and (3) the most superficial form, which is more a periostitis than a true osteitis. In this report the author gives his attention chiefly to this last metastatic staphylococcic periostitis. He describes the histories of six cases, the dominating characteristic of which is the superficial nature of the lesions; only the surface of the bone is touched by the staphylococcic infection. The roentgenograms show a localized periosteal thickening at a point of the diaphysis and this periosteal reaction remains isolated and is not accompanied by even a limited cortical destruction. The patients had been treated for cutaneous suppurations, when they complained of painfulness and slowly a tumefaction appeared. The therapy was indicated by the roentgenologic and clinical aspects. Following the simple incision of the periosseous abscess, the development was uneventful in the six reported cases. Cure was rapidly established, without passage into chronicity or fistula. Thus, the prognosis seems favorable.

Therapeutic Results in Fracture of Forearm. W. Bufe.—p. 539.

Avulsion of Trochanter Minor.—According to Herzog, avulsion of the trochanter minor is now more frequent than was formerly the case. He is convinced that the better recognition since the beginning of the roentgenologic era has not been entirely responsible for the greater incidence but that the increase in athletic activities is largely accountable, because nearly all recently observed cases were sustained in the course of athletic games. The occasions and movements that lead to avulsion of the trochanter minor are usually so similar that this lesion can be regarded as a typical injury from sport. The author describes the clinical histories of two youths aged 17 and 13 who sustained trochanteric avulsion, the one in the course of a hockey game and the other during a football game. That young persons are especially prone to sustain an "isolated" avulsion of the trochanter minor is due to the fact that during these years the epiphysial line of the trochanter minor is the site of least resistance to traction in that the mechanical system, which consists on the one hand of the iliopsoas muscle and the portions of the femur, reaching from the sites of attachment of this muscle to the hip joint and, on the other hand, of the bony pelvis and the vertebral column. This locus minoris resistentiae changes during the different ages. After ossification of the epiphysial line, during maturity, the muscle is the part that is most readily injured, and muscular strains and tears occur. Beyond the age of 50 the bone has the least resistance, and fractures of the trochanter minor may develop. Avulsion of the trochanter minor occurs almost exclusively in young persons who are less than 18 years old. This is understandable if it is considered that at about the age of 18 osseous fusion takes place between the trochanter minor and the femur. Discussing the mechanism of the trauma that elicits the trochanteric avulsion, the author shows that the force which results in the tearing away is elicited by aborted reflex movements; that is, an evolving movement is suddenly changed into a different one. Following a discussion of the clinical signs, he shows that the roentgenologic aspects are decisive for the diagnosis. The prognosis is favorable. Conservative treatment always results in osseous fusion. The patient is placed so that the knee and the hip are slightly bent and the thigh is rotated slightly outward. This position is retained by means of sand bags. Pains and swelling usually disappear rapidly following this immobilization. The roentgenogram reveals formation of callus after from three and one half to four weeks.

Therapy of Intermittent Claudication. P. Formijne.—p. 6231.

Favus in School Children.—Siemens and Krens deplore the lack of attention paid to the social importance of the contagious skin diseases, particularly favus. They emphasize the importance of enlightening the public and of impressing on the school boards the necessity of detecting and treating all children who have favus. They stress the following points: 1. All schools should be inspected by physicians. 2. Children with favus should be permitted to attend school only if they wear a bandage completely covering the lesions and if they can bring proof that they are undergoing regular treatment by a physician. In order to reach the cases of favus in persons who no longer attend school, ordinances should be passed which prohibit persons with favus from working in places in which they can infect others.

Cerebral Defects in Children Delivered by Cesarean Section.—Brander says that it is generally believed that the abdominal cesarean section insures against intracranial birth injuries. However, in reviewing the literature he found seventy-two cases of intracranial lesions verified post mortem in children who had been delivered by abdominal cesarean section (cases of vaginal cesarean section excluded). In some of these cases a tearing of the tentorium was discovered. There are also numerous observations on symptoms of intracranial birth injuries, such as defective intelligence, epileptiform convulsions and spastic pareses. The author describes the clinical histories of three children with mental defects who had been delivered by cesarean operation. He admits that in the cases of severe cerebral defects the hereditary conditions are not always sufficiently clear. Moreover, the reports in which the diagnosis of intracranial lesions in children delivered by cesarean operation cannot be doubted contain nothing about the obstetric complications that led to the cesarean operation. In this connection the author points out that the fetus may have been injured by attempted forceps extraction before the cesarean operation was resorted to. The same applies to cases in which prolonged labor pains, perhaps in connection with Walcher's position, preceded the operation. If at this time the head of the child was tightly wedged into the pelvic inlet it may be injured not only before but also during the cesarean operation. Intracranial birth injuries in connection with the cesarean operation occur more frequently in vaginal than in abdominal cesarean section, and of the abdominal methods the corporal involves less dangers for the fetus than does the cervical method. Moreover, the extraction by the foot seems to be more dangerous than freeing the head first, and instrumental development of the head is of course more harmful than is its manual extraction. In cases in which the fetus is large, too short incisions may increase the danger of an intracranial lesion. Complications may arise if the surgical incision injures the placenta. The danger of intracranial hemorrhages in the course of cesarean operations is greater in premature deliveries, in the hemorrhagic diathesis and in pregnancy toxicoses. Asphyxia supposedly may cause intracranial hemorrhages; on the other hand, it is probable that intracranial injury may become manifest in asphyxia. That methods of resuscitation may cause intracranial hemorrhages in children delivered by cesarean operation has likewise been observed. Moreover, in two reported cases of fatal intracranial hemorrhages after cesarean delivery, uterine tumors were discovered.

COMPLICATIONS DUE TO ARSENICAL THERAPY IN SYPHILITIC PREGNANT WOMEN

REPORT OF SEVEN MATERNAL DEATHS

NORMAN R. INGRAHAM JR., M.D.

Assistant Physician, Antepartum Clinic, Philadelphia General Hospital, and Associate in Dermatology and Syphilology, University of Pennsylvania School of Medicine

PHILADELPHIA

Recent writings convey the impression that pregnant syphilitic women tolerate arsenical therapy well.[1] In fact, the fear of serious reaction to the intravenous treatment of these patients with the arsphenamines has become so remote that some authorities recommend this prophylactic procedure for the unborn child, even "on suspicion" that the prospective mother may be diseased.[2] McCord,[3] who has apparently never seen a serious treatment reaction or death in the medical supervision of more than 2,000 syphilitic pregnant women, remarks that "such therapy seems to be safe for the mother." The Cooperative Clinical Group, with Cole [4] as spokesman, feels that, regardless of antecedent therapy, in order to insure the birth of a healthy child it is desirable to treat intensively throughout each pregnancy every woman who has ever had syphilis, whether the serologic tests of the blood for syphilis are positive or negative or the infection is early or late. Hoffmann,[5] voicing the opinion of one of the most progressive schools of European medical thought, in his recent lecture in this country goes one step further, recommending that "one or two combined courses should be given as a protection to the offspring" of an apparently well mother, notwithstanding "the absence of diagnostic signs and the presence of a negative serum reaction," provided her husband is known to be syphilitic.

In prescribing antisyphilitic therapy for a pregnant syphilitic woman, consideration of the well-being of the prospective mother should take precedence over the health of the unborn child, as in all other obstetric procedures. The infected woman, under medical observation and treatment during nine months at the most, and on an average during only three or four months of her pregnancy, cannot hope to have her disease cured or in most cases even materially benefited. In all except an occasional case therefore the physician is concerned with a purely prophylactic procedure, employed to prevent the offspring from becoming diseased. Without in any way denying that the treatment of the pregnant syphilitic woman to prevent her infant from becoming infected in utero is one of the most effective forms of preventive medicine known today, it should be used with caution if the hazard to the mother is appreciable.

Many of the current opinions concerning the fact that "the pregnant syphilitic woman is a good risk for arsenical therapy" are gleaned from the statistics obtained by an analysis of the records of some 4,600 injections of arsphenamine administered to 603 expectant mothers at the five university clinics (Johns Hopkins, University of Pennsylvania, University of Michigan, the Mayo Clinic and Western Reserve University) cooperating with the United States Public Health Service.[6] They found no significant difference in minor arsenical reactions in the pregnant and nonpregnant groups, but the pregnant women experienced fewer severe arsenical reactions than the nonpregnant (3.08 per thousand injections for the latter, as compared with 0.87 for the former).

This point of view, however, is not without its opponents. To mention only a few of the more recent, Stokes [7] says: "There is no doubt in my mind that the pregnant woman is not eligible, in general, for strenuous treatment regimens. The pregnant woman should not be overloaded and any signs of reactivity must be taken more seriously than in the normal case." Certain circumstances "may make it preferable to take chances for the child with heavy metal or even no treatment rather than risk the mother's life with a standardized system" (see also Wile and Shaw [8]). As a result of their studies, Plass and Woods [9] were forced to conclude "that pregnant syphilitic women are more susceptible to the deleterious, as well as to the beneficial, effects of antisyphilitic therapy by modern arsenicals than other individuals." Kuhnel [10] has gone even further in suggesting that "it may be necessary for us to modify our therapeutic view of the prophylactic and syphilitic treatment in pregnancy" (see also Woods [11]).

While the fact has always impressed me that special care is necessary in handling the syphilitic pregnant

woman, the realization of the importance of this question has recently been reemphasized by Dr. Philip F. Williams, who called my attention to the seven maternal deaths directly attributable to arsenical therapy which have been reported in one locality since 1931 to the Committee on Maternal Welfare of the Philadelphia County Medical Society. In addition, a careful review of the statistics obtained from the administration of 6,345 injections of neoarsphenamine to 733 pregnant syphilitic women during the last five years at the Philadelphia General Hospital revealed a much higher incidence of treatment reactions than is generally attributed to this type of therapy among such patients.

Several additional circumstances made it seem worth while to discuss this problem. In the first place there are in the literature relatively few series of cases large enough to warrant the drawing of accurate conclusions concerning the incidence of treatment reactions among pregnant syphilitic women. Then at least one group of observers tended to collect data only from patients who had been under observation for at least six months.[12] Many pregnant syphilitic women remain under observation for a shorter period than this, particularly if they are intolerant of arsenical therapy. Furthermore, the incidence of reactions probably varies greatly, depending on the economic status of the patients, their state of nutrition and their environment. Thus a patient at Philadelphia General Hospital would be expected to react differently from one at a university clinic or a private patient, and conclusions drawn for one group could not always be transferred directly to the next. Moreover, I am forced to the conclusion, from various references in the literature, that severe treatment reactions among pregnant women are much more frequent than is generally supposed.[10] Thus, McKelvey and Turner [13] and Moore [14] both mentioned the four deaths from acute yellow atrophy of the liver which followed arsenical therapy of syphilitic pregnant women at the Johns Hopkins Hospital. Clason [15] referred to eclampsia in one of his cases as being precipitated by arsenical therapy. Klaften [16] and Reif [17] both described patients with symptoms of hemorrhagic encephalitis who recovered. Spillmann, Weille and Weissmann [18] referred to a young pregnant woman with early syphilis in whom hemiplegia developed during arsenical therapy. Audebert and Fabre [19] reopened the question of erythrodermia and dermatitis complicating antisyphilitic therapy of pregnant women. Finally it is entirely possible that delayed arsenical reactions resulting from treatment during pregnancy, for example damage to the liver or bone marrow, the symptoms of which often take several weeks to appear, have not uniformly been recorded as reactions resulting from treatment during pregnancy when the initial symptoms have appeared after delivery. If this is true, it would lead to a false impression as to the incidence of more severe types of reaction among treated syphilitic pregnant women.

TABLE 1.—*Treatment Reactions Complicating Arsenical Therapy of 733 Pregnant Syphilitic Women at Philadelphia General Hospital, as Compared with the Statistics of the Cooperative Clinical Group [6] on Syphilitic Mothers "Not During Pregnancy"*

Reactions	Philadelphia General Hospital: Number of Reactions (6,345 Injections)	Philadelphia General Hospital: Rate per Thousand Injections	Cooperative Clinical Group [6]: Rate per Thousand Injections (6,431 Injections)
Gastrointestinal disorders	144	22.75	6.22
Nitritoid crisis	24	3.79	3.73
	8	1.26	1.71
	27	4.27	4.04
kidneys	14	2.61	0.16
Purpuric phenomena (with	7	1.11	0.00
Se	1	0.16	0.00
	2	0.32	1.40
Icterus	8	1.26	0.62
Death (colloidoclastic shock)	1	0.16	0.00

In this series there was no evidence that pregnant syphilitic women tolerate arsenical therapy well. Only in the case of generalized exfoliative dermatitis was the incidence appreciably lower than in the nonpregnant group. Here again the duration of therapy was probably an important factor, since such a reaction usually occurs after a longer course of arsphenamine than these

TREATMENT REACTION: IN THE ANTEPARTUM SYPHILIS CLINIC OF PHILADELPHIA GENERAL HOSPITAL

Table 1 summarizes five years' experience with treatment reactions in the antepartum syphilis clinic at the Philadelphia General Hospital. The group studied was roughly one third white and two thirds Negro. Unfortunately it was not possible for me to obtain data as to the total incidence of treatment reactions in the type of nonpregnant patients attending the general syphilis clinic of his institution, and it may be that this figure also is higher than normal. In order to make my own statistics somewhat more understandable, however, I have incorporated in the table the reaction rate per thousand injections from the figures of the Cooperative Clinical Group for syphilitic women treated between their pregnancies; it happens that an almost identical number of injections were given to each of these groups. This comparison brings out strikingly the facts which have been noted previously by various investigators,[20] namely the pregnant woman's increased susceptibility to gastrointestinal reactions, to irritation of the kidneys and to hepatic insufficiency. In pregnant women nausea, vomiting and diarrhea as a result of arsenical therapy are roughly three and one half times more frequent, jaundice is twice as frequent and evidence of kidney strain is about sixteen times more frequent than in nonpregnant women. It is interesting to note that among the women treated at the Philadelphia General Hospital the incidence of gastrointestinal disturbances was twice as great, of pruritus and cutaneous eruptions three times and twice as great, respectively, and of icterus six times as great as in the series of pregnant women whose cases were reported by Cole and his co-authors.[6]

patients received (average 8.4 injections). In the two cases in this series in which this manifestation did occur, it developed at about the time of delivery and extended some weeks into the puerperium.

The number of pregnant syphilitic women who become nauseated and vomit after neoarsphenamine treatment is noteworthy. This reaction is rarely an indication for suspension of arsenical therapy or even for reducing the dose. In my 733 cases the severity of this reaction made it necessary to stop intravenous injections in twelve cases. Nine additional patients were carried along with little discomfort by reducing the size of the dose and administering 1/100 grain (0.6 mg.) of atropine sulfate. Irritability of the kidneys likewise is not an indication for cessation of treatment unless the patient shows evidence of toxemia of pregnancy, such as increasing hypertension, headache, disturbance of vision, marked albuminuria or edema of the ankles. In the presence of definite or incipient toxemia it has been my experience that no type of antisyphilitic therapy is well tolerated, and, since the risk in administration of these drugs is great to a patient whose elimination is poor, it is best to discontinue antisyphilitic treatment entirely. The jaundice which I have seen has occurred close to term and, on the cessation of arsenical therapy, has cleared up post partum without evidence of permanent hepatic damage. The death recorded in table 1 is that in case 4, described subsequently.

MATERNAL MORTALITY FROM ARSENICAL THERAPY DURING PREGNANCY

In an effort to demonstrate that the pregnant syphilitic woman is by no means immune to the serious treatment reactions attending antisyphilitic therapy and to suggest, moreover, that she may be, as some authors feel, more susceptible than the nonpregnant woman, thirty-five reported cases have been collected and summarized, and the seven cases discussed before the Maternal Welfare Committee of the Philadelphia County Medical Society have been briefly analyzed. The cases gathered from the literature include the twenty-three described in detail by Kühnel,[10] the case of eclampsia reported by Clason,[15] the cases of exfoliative dermatitis of Lorenzen [21] and Kirstein [22] and the cases reported by Scheel,[23] Neustadt,[24] Cole and his associates,[25] Plass and Woods,[9] Cormia,[26] Gierlich and Künkele [27] and Lanzenberg and Laugier.[28]

These forty-two cases represent most of the known types of serious arsenical complications (table 2). In almost two thirds the condition falls into the category of acute encephalopathy, which has come to be termed in the literature acute hemorrhagic encephalitis because of the intense cerebral congestion revealed by autopsy (wet brain with multiple punctate hemorrhages [29]). The fact that pregnant syphilitic women are particularly susceptible to this type of treatment reaction was early recognized by Meirowsky,[30] Gammeltoft [31] and Klaften,[16] and the question has recently been reviewed by Cormia [26] and by Plass and Woods.[9] Kühnel [10] has given a graphic description of the condition, which, coming on in the latter part of the pregnancy, most often after from one to three arsenical injections to a woman with early syphilis, with the symptom sequence of headache, vertigo, malaise, nausea, vomiting, hyperpyrexia, clonic convulsions, unconsciousness, cyanosis and death within twenty-four to seventy-two hours, forms a distinctive clinical entity.[31a]

TABLE 2.—*Cause of Thirty-Five Fatal Arsenical Reactions Collected from the Literature, with Seven Additional Cases from the Philadelphia County Medical Society*

	From Literature	My Cases	Total	Percentage
Acute encephalopathy (hemorrhagic encephalitis)	24	3	27	64.3
Acute circulatory collapse (colloidoclastic shock)	2	2	4	9.5
Parenchymatous degeneration of the liver (and kidneys)	2	1	3	7.1
Arsphenamine dermatitis	2	..	2	4.8
Aplastic anemia	0	1	1	2.4
Eclampsia (precipitated by antisyphilitic therapy)	1	..	1	2.4
Cause unknown	4	..	4	9.5
	35	7	42	100.0

Acute circulatory collapse most often follows the second or third arsenical injection and presents the picture clinically of colloidoclastic shock described by Orr [32] and Weinberg [33] and pathologically of dilatation and intense congestion of all peripheral vessels (case 4). In both cases,[34] of arsphenamine dermatitis the condition was complicated by pyodermia and puerperal sepsis developing post partum. Eclampsia accompanying arsenical therapy or precipitated by it may be more frequent than the single case recorded by Clason [15] would indicate. In connection with the case of aplastic anemia (recorded subsequently) it should be noted that definite symptoms of the condition did not develop for from four to eight weeks after delivery and that in a statistical compilation it would be easy to overlook such a condition as resulting from arsenical therapy during pregnancy.

REPORT OF CASES

CASE 1.—*Death from aplastic anemia.*[34a] *History.*—An apparently healthy white woman aged 18, reported Oct. 2, 1936, for antepartum supervision during the fourth month of her

34a. Mortimer Goldberg (Am. J. Syph., Gonor. & Ven. Dis. **23**: 79 [Jan.] 1939 has recently reported a case of bone marrow injury from neoarsphenamine therapy in a syphilitic pregnant woman with recovery.

second pregnancy. The previous pregnancy, which terminated Nov. 5, 1935, had resulted in a living infant with congenital syphilis. The mother's infection was latent; serologic study of the blood at the time of the first visit showed the Kolmer reaction 44 and the Kahn 444. The stage of the disease was unknown, but it was probably early. Her antepartum course was uneventful, except that she showed a trace of albumin in the urine on five different occasions in late pregnancy. The blood pressure varied between 94 and 120 mm. of mercury systolic and 48 and 84 diastolic. She was delivered of a normal infant after seven hours of labor March 9, 1937. Her hemoglobin concentration was 81 per cent immediately post partum.

Antisyphilitic Therapy.—During pregnancy, from Oct. 2 to Nov. 6, 1936, she received six 2 cc. injections of bismuth subsalicylate (each cubic centimeter equals 60 mg. of metallic bismuth). From Nov. 13 to March 6, 1937, she received concurrent treatment with triarsen [35] and a bismuth preparation (total, twelve injections of triarsen [5.75 Gm.] and sixteen injections of bismuth salicylate [31 cc.] without reaction. She received no treatment for syphilis post partum.

Course.—She was readmitted to the hospital May 17, 1937, because of vaginal bleeding, which had continued since the birth of the child, gradually becoming worse, with recent abdominal pain and passage of clots, bleeding gums for one month, epistaxis, and purpuric spots on the arms and lower extremities of six weeks' duration. At the time of admission gingival ulcerations were noted. There was abundant albuminuria from May 19 to death. The results of studies of the blood are shown in table 3. Transfusions were given May 19, 22 and 26, but the patient died with marked hyperpyrexia (temperature 105 F.) May 27.

TABLE 3.—*Results of Studies of the Blood in Case 1*

Date	Erythrocytes	Hemoglobin, %	Leukocytes	Neutrophils	Lymphocytes	Monocytes	Transitional Forms	Eosinophils	Basophils	Platelets
5/19/37	780,000	10	7,000	27	70	2	0	1	0	.....
5/20/37	1,840,000	35	6,000	17	80	2	1	0	0	82,600
5/21/37	.....	45	.....	40	60	.	.	..	..	.....
5/25/37	2,960,000	58	4,000	5	95	.	.		..	92,600
5/26/37	2,000,000	40	2,600	..	..				.	. . .
5/27/37	2,360,000	50	1,800	4	96				..	. .

Autopsy.—Aplastic anemia following arsenical therapy, with generalized purpuric phenomena, was reported. The skin, mucosal surfaces and serosa showed evidence of ecchymoses throughout. There were confluent lobar hemorrhages in the lungs, acute passive congestion in the liver and follicular hyperplasia and passive congestion in the spleen. The kidneys showed extreme cloudy swelling and acute gangrenous pyelitis. Histologic examination of bone marrow gave results typical of aplastic anemia.

CASE 2.—*Acute yellow atrophy of the liver. History.*—A well developed and well nourished Negro woman aged 38 reported Jan. 7, 1936, for antepartum supervision in the twenty-sixth week of her second pregnancy. She had had a negative Wassermann reaction in another institution in January 1935, but strongly positive Kolmer and Kahn reactions were present on her first antepartum visit; the results were confirmed January 14. She gave no history of previous treatment and no history of onset of infection.

Antisyphilitic Therapy.—She received four injections of bismarsen (0.2 Gm. each) intramuscularly between January 21 and February 25 without reaction.

Course.—March 3 she was admitted to the hospital because of increasing jaundice, icteric skin and scleras, deep colored urine and clay colored stools. After admission severe gastric hemorrhage developed; the patient could retain no food taken by mouth and finally became comatose and died March 10.

Autopsy.—Syphilitic aortitis, marked jaundice and acute yellow atrophy of the liver were evident. In this case it is impossible to state whether the arsenical therapy was the sole cause or merely the precipitating cause of death, but it was felt that it played at least some part in the unfortunate outcome.

CASE 3.—*Acute circulatory collapse. History.*—A Negro woman aged 32 reported in January 1933 for antepartum supervision in the twenty-sixth week of her third pregnancy. Serologic study of the blood gave strongly positive results at the time of her first visit (Kolmer 44, Kahn 444). The duration of her disease was unknown, but she was found to have a positive serologic reaction of the blood for syphilis in another institution in 1927 and had received arsenical therapy for thirteen weeks at that time, with none since. Complete cardiovascular study March 15 showed possible syphilitic aortitis and signs of "potential" myocardial involvement.

Antisyphilitic Therapy.—April 1 she received 0.025 Gm. of bismarsen intramuscularly, April 8 0.3 Gm. of neoarsphenamine and April 15 0.45 Gm. of neoarsphenamine, without reaction. With the third injection (0.45 Gm.) of neoarsphenamine, given April 22, she became dyspneic and cyanotic while in the treatment room, with a fall of blood pressure and rapid almost imperceptible pulse. She became comatose within a few minutes and, although admitted to the hospital immediately and given emergency stimulative treatment, died within an hour.

Autopsy.—Syphilitic aortitis and coronary and myocardial involvement were present, with acute dilatation of the heart. There was generalized acute passive congestion. Death may have been due to coronary insufficiency, the result of the rapid healing fibrosis of therapeutic paradox, but the sudden onset of symptoms during injection also brings up the question of acquired arsenical intolerance. The brain was not examined. Nothing observed ante partum among the terminal symptoms or at autopsy suggested toxemia of pregnancy.

CASE 4.—*Acute circulatory collapse. History.*—An apparently healthy Negro woman aged 22 reported to the antepartum clinic during the fourth month of her fifth pregnancy. Kahn and Kolmer-Wassermann tests performed November 3 and on two subsequent visits gave negative results. She was known to have syphilis, however, having first been discovered to have a positive serologic reaction of the blood in 1931. She had had no arsenical treatment during her first pregnancy, two months of arsenical therapy during her second, nine months of arsenical and heavy metal therapy during her third, and two months of arsenical therapy during her fourth. She had had no treatment for syphilis for one year prior to her present conception and would have been considered clinically "cured." In view of the fact that she had tolerated previous treatment well, and since she appeared in good health and normal on physical examination, it was decided to treat her for the sake of her child. Antepartum supervision between Nov. 3, 1937, and Jan. 12, 1938, revealed normal blood pressure and urine and no evidence of toxemia of pregnancy.

Antisyphilitic Treatment.—Neoarsphenamine 0.3 Gm. was given intravenously Jan. 12, 1938, with no reaction; 0.45 Gm. was given January 19.

Course.—Ten minutes after her second injection she complained of acute abdominal pain and collapsed on the floor. Within five minutes she lost consciousness; the skin became cyanotic, cold and clammy and the pulse rapid and thready. The blood pressure, at first maintained, became rapidly lower. She exhibited muscular twitching and choreiform movements and in spite of stimulative treatment (epinephrine, atropine, caffeine) died within one hour.

Autopsy.—There was no evidence of syphilis in any of the organs. The picture was that of acute circulatory collapse, with generalized capillary dilatation. The lungs, spleen, liver and kidneys showed intense acute passive congestion. The heart, coronary vessels and aorta were normal. The bones of the skull were hemorrhagic, the dural sinuses were dilated and there was intense congestion with subarachnoid hemorrhage. The brain was intensely edematous, with hemorrhages into the ependymal lining of the ventricles. It was felt that the intracranial as well as the general systemic picture was merely attendant on the acute circulatory collapse.

35. Stokes, J. H., and Beerman, Herman: New Arsphenamine Synthetics in the Treatment of Syphilis: A Consideration of Test Procedure and of a New Drug (Triarsen), Arch. Dermat. & Syph. **35**: 78 (Jan.) 1937.

CASE 5.—*Acute encephalopathy. History.*—A Negro woman aged 30, married, in good general health, reported for antepartum supervision in the sixth month of her third pregnancy. On the first visit she was discovered to have weakly positive Kolmer and Kahn reactions. She gave no history of antecedent antisyphilitic therapy, and the duration of her infection was unknown. Her blood pressure and urine were always normal.

Antisyphilitic Treatment.—Neoarsphenamine 0.3 Gm. October 8 and 0.6 Gm. October 15 was given without evidence of intolerance.

Course.—Two days after the last injection she was admitted to the hospital because of dizziness and pain in the lower part of the abdomen. October 18 she had a bilateral convulsion lasting ten minutes and three hours later two generalized convulsions of short duration, following close one on the other. She was unconscious thereafter until death, some five hours later. There were no clinical or laboratory signs of eclampsia; a normal living child was delivered immediately after the death of the mother.

Autopsy.—Nothing significant was observed except evidence of acute encephalitis, with exudation and capillary hemorrhage, and parenchymatous cerebral syphilis. It is impossible to state in this case whether death resulted from therapeutic shock (Herxheimer reaction) in an area already diseased from syphilis or from the hemorrhagic encephalitic syndrome, so frequently described as complicating arsenical therapy among pregnant women. Death apparently did not result, however, from a massive intracranial hemorrhage or from any gross single lesion.

CASE 6.—*Acute encephalopathy. History.*—A healthy young white woman aged 24 reported for antepartum supervision Oct. 21, 1932, during the sixth month of her first pregnancy. Syphilis was diagnosed by means of a strongly positive Wassermann test, confirmed. The duration of the disease was unknown.

Antisyphilitic Therapy.—Neoarsphenamine 0.5 Gm. October 31 and 0.5 Gm. November 14 was given without reaction.

Course.—Shortly after the second injection the patient became nauseated and vomited, the reaction continuing until she was admitted to the hospital November 16. At this time she complained of severe headache and was restless, stuporous and markedly spastic. Before death twenty-four hours later she became unconscious and cyanotic and had focal and generalized convulsions; her temperature rose from 102 F. on admission to 106 at the time of death. Complete laboratory studies gave no evidence of eclampsia. There was no albumin in the urine. The blood showed sugar 120 mg., urea 13 mg., urea nitrogen 9.4 mg., creatinine 2.7 mg., calcium 8 mg. and phosphorus 3.5 mg. per hundred cubic centimeters. The blood pressure varied between 112/60 and 130/60. In the cerebrospinal fluid there were 1 mg. of globulin, no sugar, 1 cell and 2 mg. of albumin per hundred cubic centimeters.

Autopsy was refused. In this case the clinical picture was typical of that described by Kuhnel [10] and others as complicating arsenical therapy of syphilitic pregnant women.

CASE 7.—*Acute encephalopathy. History.*—A white woman aged 31 reported for antepartum supervision in the sixth month of her fourth pregnancy. She gave no history of syphilitic infection or of previous treatment, but four consecutive serologic tests of the blood were reported to show medium positive Kolmer, Wassermann and Kahn reactions between Aug. 26 and Sept. 16, 1933. On the basis of these tests a diagnosis of latent syphilis of unknown duration was made and treatment started. The Wassermann reaction had been negative in 1930.

Antisyphilitic Therapy.—Neoarsphenamine 0.3 Gm. September 23 and 0.45 Gm. September 30 was given.

Course.—The night following the second injection she had a severe headache and high fever but the next day she felt better. October 2 she again felt dizzy and she went to bed and slept. On awaking she found that she could not talk and was too weak to get up, and when she attempted to move she had a convulsive seizure involving the left side of the body. She was admitted to the hospital the same day and showed left hemiplegia. It was the opinion of the syphilologic staff that such a lesion could have been caused by cerebrovascular therapeutic shock (Herxheimer reaction). She died October 4. Before death her temperature rose from 98 to 104 F. and the blood pressure from 104/80 to 150/100. The urine showed a cloud of albumin during the febrile period; the blood, 124 mg. of sugar and 24.7 mg. of urea nitrogen per hundred cubic centimeters. In the cerebrospinal fluid the colloidal goid curve was 0000000000, the Wassermann reaction negative and the pressure 8 mm. of mercury; there were 37 cells and 3 mg. of globulin per hundred cubic centimeters. It was felt that neither the symptoms nor the laboratory data were indicative of toxemia of pregnancy.

Autopsy was refused. This case likewise would seem to be one of a cerebrovascular lesion resulting from arsenical therapy during pregnancy.

COMMENT

A critical analysis of the medical handling of the foregoing forty-two cases of maternal death following antisyphilitic therapy during pregnancy reveals many interesting facts. The age of the patient and her parity apparently have little influence on the fatal termination. The fact that 31 per cent of the patients were under 21 and 69 per cent under 28 years of age is probably no more than a reflection of the truth that the young women bear the children and that the maximum incidence of syphilis in this country is between the ages of 21 and 28. It does suggest, however, that mere youth and the general appearance of physical well-being by no means exclude the possibility of a serious reaction to arsenical therapy. Only two of the patients were over 36 years of age. Multiparas and primiparas suffered almost equally, 58 per cent of the former and 42 per cent of the latter comprising this series.

TABLE 4.—*Type of Infection at the Onset of Antisyphilitic Therapy in Forty-Two Fatal Cases*

	Number	Percentage
Syphilitic		
Symptomatic early (primary or secondary)	16	38.1
Latent of less than four years' duration	4	9.5
Latent of more than four years' duration	7	16.7
Latent (duration unknown)	13	30.9
Symptomatic late	1	2.4
Nonsyphilitic	1	2.4
	42	100.0

An analysis of the statistics, moreover, with regard to the duration of syphilis at the time of the onset of therapy reveals the surprising fact that in almost one half of the cases the physician was concerned with early syphilis, primary, secondary or latent of less than four years' duration (table 4). In more than half of the remaining cases the disease was a symptomless infection of unknown duration, so that in actuality in only eight instances (19 per cent) was the disease known to be more than four years old. Death resulted in one case in which syphilis had not been proved, therapy being administered merely because the husband was found to be infected. Instances of this sort and like case 4 bring into serious question the advisability of intensive arsenical therapy when the chances of infection of the child are so meager, even though the prospective patient gives outwardly the appearance of a good treatment risk. Although the series of cases was too small to permit of any sweeping conclusions, it is worth while to note in this connection that the fifty-two mothers in the Cooperative Clinical Group [6] study who became pregnant after having had sufficient treatment to be considered "cured" had no syphilitic children among those born up to fifteen years after infection,

even though not treated during each subsequent pregnancy. Hoffmann's [36] considerable experience in this regard should also be considered. He said "A new course of treatment is not necessary in later pregnancy in women who have been treated intensively and systematically and whose cure may be assumed with sufficient probability."

Of this series of fatal cases treatment was started during the first four calendar months in 12 per cent, during the fifth or sixth month in 41 per cent and after the sixth month in 47 per cent. This again is nothing more than a confirmation of the circumstance frequently noted before in the literature, that pregnant syphilitic women report for antisyphilitic therapy late in pregnancy. It is usually necessary as a result of this to commence treatment when the physical burden of the woman in bearing her child is already well advanced. Only eight (19 per cent) of these patients had had antisyphilitic treatment prior to the pregnancy, two (4.7 per cent) had received more than twenty arsenical injections and six (14.3 per cent) had received less than this amount.

TABLE 5.—*Number of Arsenical Injections After Which First Clinical Symptoms Appeared in Forty-Two Instances of Maternal Death*

Number of Injections	Cases	Percentage
One	5	11.9
Two	19	45.2
Three	10	23.8
More than three	8	19.1
	42	100.0

This fact brings up at least three important points for consideration: (1) preparatory treatment, (2) the question of individual intolerance or idiosyncrasy and (3) the ability of the already burdened pregnant woman to cope with the additional strain of antisyphilitic therapy.

When it is considered that one third of these women presented symptomatic early syphilis (primary or secondary) during their pregnancy and that only two showed evidence, either clinically or pathologically, of any serious late complication of the disease, it is probable that in most instances preparatory treatment with a heavy metal (a mercury or a bismuth preparation) prior to the institution of arsenical therapy was seldom seriously considered. Thirty-nine per cent of the patients received some preparatory treatment and 61 per cent none. It should, however, be pointed out that attempts to prepare patients for arsenical therapy have been inadequate, consisting for the most part of one or two injections of a heavy metal or their equivalent at from five to seven day intervals. According to present notions no less than from two to three weeks' treatment with a water-soluble heavy metal mercury or bismuth preparation in an adequate dose two or three times weekly or three or four weekly injections of an oil-suspended preparation (e. g. bismuth subsalicylate) could be expected to offset the shock of onset of arsenical therapy.

One of the most striking features of the entire analysis is the revelation that 81 per cent of these fatal treatment reactions were precipitated by three or less arsenical injections (table 5). In the majority of the remaining cases death resulted from damage to the liver, changes in the bone marrow or complications of exfoliative dermatitis which not infrequently require a number of days for development of clinical symptoms. Death likewise has been a matter usually of only hours or days (table 6). In only two instances in the series could the dose of the drug employed have been considered excessive, and this not markedly so (e. g. 0.5 Gm. of neoarsphenamine at five day intervals). Death following shortly after a single arsenical injection brings up for consideration the possibility of atopic drug allergy, and instances in which the symptoms with fatal termination followed closely the second or third injection suggest sensitization (acquired allergy). Such speculation finds further confirmation in the pathologic observations in many of these cases, consisting only of extreme peripheral congestion of acute circulatory collapse, with the hemorrhagic phenomena in the brain and other organs of capillary anoxemia or intoxication and increased permeability of the vessel walls. Whether the pregnant woman is more susceptible to the major and minor complications of arsenical therapy than the nonpregnant one is a matter on which there is still considerable difference of opinion among physicians. I feel that I have advanced evidence from my personal experience and from the literature which would indicate that at best the pregnant syphilitic woman is only a moderately good risk for arsenical therapy. Certainly principles of treatment which would be considered invalid for nonpregnant women (e. g. the onset of arsenical therapy in full dosage without adequate preparation in a case of late syphilis or of latent syphilis of unknown duration) should not be employed in the management of a syphilitic pregnant woman in the general haste and eagerness for protecting the unborn child.

Finally, both in the cases collected from the literature and in those reported locally there is much to indicate that the severity and the unusualness of the type of treatment reactions described in this paper, occurring usually in an obstetric service, resulted too often in an unwarranted delay and at times in almost complete omission of recognized emergency therapy. While this is neither the time nor the place for a detailed discussion of the management of severe arsphenamine reactions, it cannot be overemphasized that if colloidoclastic shock, for example, is to be successfully combated, a matter of a few minutes hesitation in the onset of treatment with warmth and slow intravenous administration of dextrose (from 10 to 15 per cent solution) may be crucial. With hemorrhagic encephalitis epinephrine therapy with venesection and spinal drainage is successful ordinarily only when commenced before repeated convulsive seizures develop and before the

TABLE 6.—*Time After Commencement of Arsenical Therapy at which Clinical Symptoms and Death Occurred*

patient becomes comatosed. These severe treatment reactions are to be considered extremely serious but never hopeless if handled with dispatch.

SUMMARY

Statistics taken over a five year period in a large general hospital where the general principles involved in the teachings of the Cooperative Clinical Group on the management of syphilis in pregnancy are rigidly adhered to would indicate that under certain circumstances or with certain classes of patients during pregnancy there is a markedly greater incidence of treatment reactions than with other reported groups.

That this higher incidence of treatment reactions is not a peculiarity of the institution from which this series emanates is suggested by the seven maternal deaths from antisyphilitic therapy reported from six different sources to the Committee on Maternal Welfare of the Philadelphia County Medical Society since 1931.

An analysis of the statistics pertaining to the thirty-five additional deaths collected from the literature indicates that the pregnant woman is not exempt from any of the severer types of treatment reaction, hemorrhagic encephalitis, acute circulatory collapse, damage to the liver, arsphenamine dermatitis and aplastic anemia all having occurred with fatal termination. There is, moreover, evidence to indicate that antisyphilitic therapy may aggravate an already existing toxemia or precipitate an incipient one.

This presentation is not intended in any way to depreciate the value of antepartum antisyphilitic therapy in protecting the unborn child in utero. All the authoritative literature indicates that at present the treatment of infected pregnant women forms one of the best imaginable fields of preventive medicine.

The added impetus of the public health movement for control of venereal disease, and especially the attention directed toward syphilis in pregnancy by the numerous state antepartum and premarital Wassermann laws under discussion, will tend of necessity, for a time at least, to direct the treatment of many syphilitic pregnant women away from the medical specialists in this field. While it is undoubtedly true that, with a rare degree of intuitiveness, individualization and attention to detail such as may be expected from the expert it is possible safely to treat syphilitic pregnant women with arsenicals, the facts contained in this study would seem to suggest that it is hardly proper to state that these women tolerate such therapy as well as or better than average.

The fact that these unfortunate symptoms have tended to occur among young patients with early or symptomless syphilis indicates that even with such patients, who if not pregnant would be expected to tolerate active therapy well, it is advisable to administer arsenical treatment cautiously, starting with small doses and gradually increasing them. Moreover, since for the pregnant woman the drug is ordinarily not curative but prophylactic for her child, it would possibly be advisable to give more consideration to adequate preparatory heavy metal therapy before commencing active arsenical treatment, even though one is confronted with an early infection in late pregnancy.

In addition, the question is raised as to whether active arsenical therapy is indicated at all during pregnancy unless there is reasonable assurance that the prospective infant has a strong chance of being diseased.

REDUCTION OF MATERNAL MORTALITY IN CLEVELAND

RICHARD A. BOLT, M.D., DR.P.H.
Director of the Cleveland Child Health Association and Associate in Hygiene and Preventive Medicine and in Pediatrics at Western Reserve University School of Medicine
CLEVELAND

Has there been an actual reduction in the maternal mortality rate in Cleveland or only a fictitious one? The answer requires a critical analysis of all the factors involved: socio-economic conditions, completeness of vital statistics, changes in classification, medical and nursing technics and adequacy of hospital facilities. Changes in the birth rate and movements of population also enter into the problem.

Prior to 1931 Cleveland, in company with other cities of comparable size, exhibited considerable variation from year to year in official maternal mortality rates (table 1). The rate varied irregularly from 4.3 to 7.2 deaths per thousand registered live births. Careful analysis of the vital statistics for the period from 1910 to 1930 indicates, as the main factors which account for this irregularity, (1) incompleteness and irregularity in the reporting of births and the misinterpretation of stillbirths, (2) a declining birth rate due to later marriages, contraception and induction of abortions, (3) inaccuracy in reporting the causes of maternal mortality and obscuring of puerperal deaths under classifications which do not readily reveal the puerperal nature of the disease, (4) changes in obstetric technics and nursing procedures, (5) availability and acceptance of antepartum care and instruction, (6) availability and use of well equipped hospitals, (7) intercurrent epidemics of diseases such as influenza, which bear most heavily on puerperal women, and (8) fundamental changes in the socio-economic order.

* 1937 rates based on data furnished by each city.

Before 1931 little attention was paid to underlying conditions influencing maternal mortality rates. In 1931 the Cleveland Child Health Association undertook a complete and detailed study of every puerperal death occurring in Cleveland. This study[1] revealed the following facts:

1. Deaths due to abortion made up one third of the puerperal deaths in 1931; in over 70 per cent of the

Read before the Child Hygiene Section of the American Public Health Association, Kansas City, Mo., Oct. 26, 1938.

cases sepsis was the primary cause of death. In classifying puerperal deaths a distinction should be made between those involving a viable and those involving a nonviable fetus, a convenient dividing line being placed at from twenty-six to twenty-eight weeks of uterogestation.

2. Puerperal sepsis, the toxemias and hemorrhages were the major causes of death and were associated largely with hurried, operative and bizarre obstetrics.

TABLE 2.—*Principal Causes of Puerperal Deaths, Arranged in Order of Their Importance, Cleveland, 1930-1937*

According to an analysis of the Cleveland Hospital Obstetric Society

		Number of Deaths	Percentage of Total
1	Abortion	151	22.53
2	Postpartum infection	103	15.37
3	Late toxemia	80	11.94
4	Hemorrhage	60	8.95
5	Ectopia	49	7.31
6	Other causes	41	6.12
7	Septic embolus	34	5.75
8	Heart disease	30	4.48
9	Early toxemia	29	4.33
10	Antepartum pneumonia	26	3.88
11	Shock	20	2.98
12	Postpartum pneumonia	19	2.83
13	Anesthetic	14	2.09
14	Nonseptic embolus	14	2.09
	Total number of puerperal deaths	670	100%

3. The maternal mortality rates varied markedly from hospital to hospital, depending on the nature of the hospital, composition of the staff, routines employed and selection of cases. The hospitals giving only maternity care showed the lowest rates. General hospitals with properly equipped and isolated maternity wards or private pavilions had the next lowest rates. The City Hospital, to which all types of patients are referred, including a considerable number of Negroes and persons from the lower economic areas, had the highest maternal mortality.

4. The midwife played a very small part in contributing to the puerperal death rate.

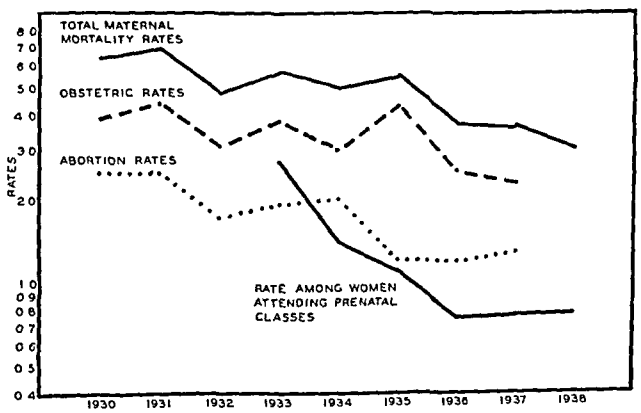

Chart 1.—Maternal mortality, Cleveland, 1930-1938 (rate per thousand live plus still births), total city rates compared with rates for women attending antepartum classes

5. The lack of antepartum care in the great majority of cases and the failure to give simple instructions in maternal hygiene was impressive. In the case of only about a third of the viable births could it be said that adequate antepartum care had been given.

There had been considerable improvement in the registration of births in Cleveland during the twenty-five years prior to 1931, so that in 1931 it was estimated that at least 98 per cent of all births were registered. At present approximately 99 per cent of all births are registered. However, there still remained considerable room for improvement in the medical certification of the causes of puerperal deaths, especially as to the relative importance of primary and secondary causes. Our study revealed that in more than 30 per cent of the cases the cause of death was not stated properly on the death certificate so as to facilitate exact classifications. A check of the death certificates of every woman dying between the ages of 15 and 45 revealed that 28 per cent more deaths occurred from causes connected with childbirth than could be discovered through the official reports.

In many cases it was not possible to discover the exact cause of death without an intimate study of the personal, clinical, hospital and nursing history. This of course required the closest cooperation from hospital doctor and nurse. The information could be obtained more readily when the death occurred in a hospital, but it was possible to secure fairly accurate information when the patient was delivered by a private physician in the home and even in the midwives' cases and those in which the coroner was involved.

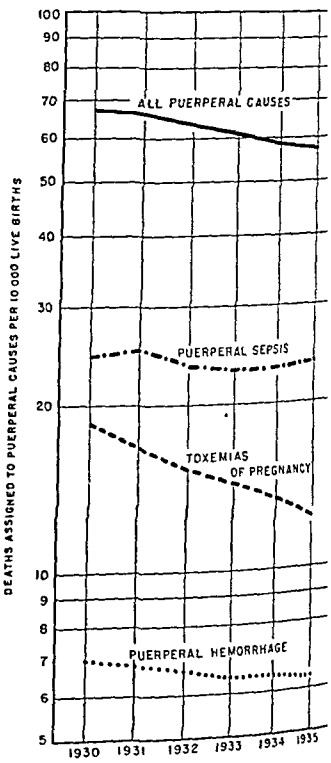

Chart 2.—Maternal mortality, 1930-1935, for the United States birth registration area of 1930 (the entire United States except South Dakota and Texas), deaths assigned to puerperal causes per 10,000 live births. Charts 2 and 3 are from the Children's Bureau, United States Department of Labor, source, United States Bureau of the Census.

March 29, 1933, the results of this study were presented to the Obstetrical and Gynecological Section of the Cleveland Academy of Medicine. The Academy of Medicine and the Division of Health took an active interest in them. A number of the chiefs of obstetric divisions of the Cleveland hospitals came together for mutual counsel as to what should be the next steps in the program. The feeling was expressed that if representatives from the obstetric staffs of each of the major hospitals would meet regularly and bring before the group case histories of women dying in hospitals from any puerperal cause, these could be discussed freely item by item and a careful analysis made of all contributing factors. This would lead naturally to an appraisal as to the preventability or nonpreventability of the puerperal deaths.

Out of the deliberations of this group arose the Cleveland Hospital Obstetric Society. The society adopted a classification of puerperal deaths based mainly on the clinical history. The causes of death are listed under sixteen different items, with qualifying classifications to clarify the factors associated with the death. Deaths

following abortions prior to six and one-half months of pregnancy are differentiated from those which occur when the fetus is viable, the so-called obstetric deaths. The toxemias are divided into early and late toxemias, and emboli are designated as nonseptic or septic. Antepartum and postpartum infections are separated whenever possible (table 2). A study has been made of the

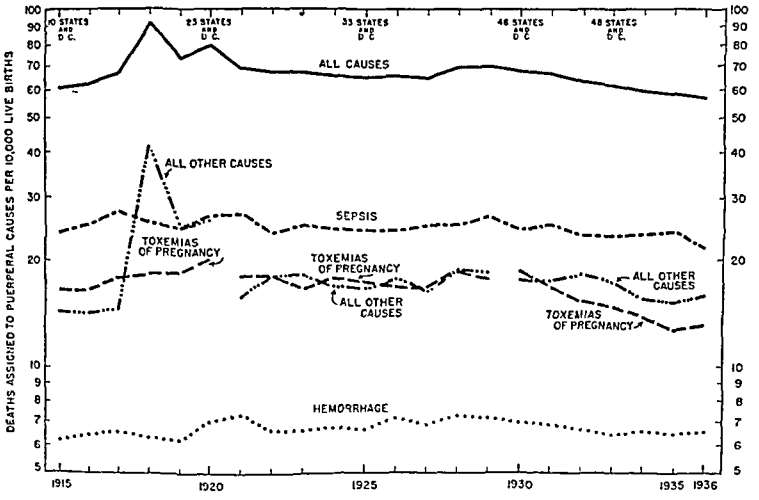

Chart 3.—Maternal mortality by cause, 1915-1936 (United States expanding birth registration area); deaths assigned to puerperal causes per 10,000 live births. The breaks in the lines are due to changes in the conditions included in the international list titles.

deaths in cases in which disease was proved to exist on entrance to the hospital.[2]

In 1934 a statewide organization was formed. The Hospital Obstetric Society of Ohio held its first regular meeting in Columbus, May 5, 1934. The program and recommendations presented by its president were adopted as guiding principles for each of the hospitals subscribing to its standards. July 21, 1937, the society adopted obstetric standards for group 1 and group 2 hospitals to strengthen the setup in the various hospitals, making for better administration, housing, staff arrangements and follow-up of all obstetric patients.[3]

The forty-five hospitals now members of the Ohio society prepare detailed monthly reports. The Bureau of Child Hygiene of the Ohio Department of Health has attached a statistician from its staff to the society to devote his full time to the study and classification of the reports dealing with the exact causes of deaths associated with pregnancy. It is hoped that the correlation of the known facts will lead to preventive measures which will save many lives.

There is no question that the efforts of the society have been instrumental in improving the practice of obstetrics in hospitals throughout the state. It must be clearly understood, however, that even before its organization Cleveland had an ample number of obstetric beds in well conditioned hospitals, the services being under competent supervision. The midwife had played only a minor part in maternal mortality, as the percentage of midwives' cases had decreased gradually from 6 in 1930 to 1 in 1937.

For many years the Maternity Hospital, now one of the university hospitals of Cleveland and the teaching obstetric hospital for Western Reserve University School of Medicine, has maintained antepartum centers in various sections of Cleveland for service to mothers in the lower economic levels. These clinics have made possible excellent antepartum medical and nursing services and care at delivery in Maternity Hospital, City Hospital or the patient's home. They reach approximately one third of all child-bearing women in Cleveland each year.[4]

The Visiting Nurse Association of Cleveland also has played a prominent part in the maternity program for many years. It sends out trained nurses to render service in the home, free to those who can pay nothing and part pay and full fee to those who can afford fees. Pregnant women are referred to the Visiting Nurse Association through private physicians, relief agencies, insurance companies, the Maternity Hospital Dispensary and sometimes by the family itself. The association follows up all postpartum calls for Maternity Hospital.

Antepartum calls of visiting nurses to patients of private physicians usually come late, as the family frequently does not call the doctor until the later months of pregnancy. The value of this service is enhanced when the physician refers his patient early. The services were organized primarily to care for the individual needs of the patient and to give individual instruction.[4]

There has been another community-wide development—group instruction of expectant mothers—which undoubtedly has played a material part in the reduction of maternal mortality in Cleveland.[5] In large antepartum clinics physicians and nurses find little time to give individual instruction. It was felt that instruction

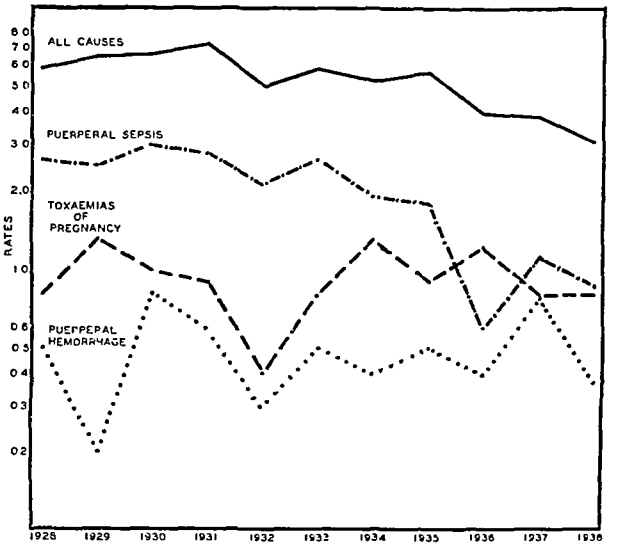

Chart 4.—Maternal mortality, Cleveland, 1928-1938; rates per thousand live births.

which might be given to women in groups would have a distinct bearing on the cooperation with the physicians and greater regularity of attendance at the antepartum clinics and secure closer check-ups at delivery than otherwise might be the case. Accordingly, in 1922

antepartum group instruction was instituted by Mrs. Ellen D. Nicely, nurse director of clinics, in the antepartum clinics of the University Public Health Nursing District.

The time of groups of mothers who were waiting their turn to interview the doctor in the clinic was occupied in listening to the nurse explain in simple language matters of hygiene, nutrition, clothing and infant care. This program was developed further under the Cleveland Health Council and the Maternity Hospital, and in 1932 it came under the direction of the Cleveland Child Health Association, where it has developed rapidly.

† Closed in 1937.

It began to be recognized that group instruction in antepartum care was just as important for the patients of private physicians as for those attending the clinics. In 1933 an experimental class for private patients was organized by the Cleveland Child Health Association in the headquarters of the Academy of Medicine of Cleveland. This proved immediately successful, and several more such classes were opened in other sections of the city. Since 1933 the antepartum lectures and craft classes have been open to any woman in greater Cleveland who wishes to avail herself of their advantages. At present 100 classes a month are being conducted, forty for the patients of private physicians and sixty for patients at clinics.

The Academy of Medicine of Cleveland has assumed joint sponsorship of the classes[6] for the patients of private physicians. No patient is accepted without an admission card signed by her physician signifying his approval. Patients of more than 300 private physicians have registered in the classes in the past five years.

An important feature of this development has been the mothercraft classes, in which the women are taught to make practical layettes at small cost. If a mother has some special problem, the instructor arranges time for a personal conference. Sometimes fears or superstitions trouble the mother and she is too timid to consult her doctor. In such cases the instructor tries to put her in a proper frame of mind to consult her physician. Our experience has been that these classes and personal conferences are of great value, as they ease the mind of the expectant mother, giving her a clear picture of what is before her and of many things that have appeared vague. Furthermore they make possible a check of her simple disorders and unfavorable signs and place the instructor in a position to refer her immediately to her family physician or obstetrician for observation and treatment.

Year by year the women are coming to the classes earlier in pregnancy and are attending more and more of the lectures. In the past five years there has been a gain from 11 to 17 per cent in the number of women registering in the classes during the first three months of pregnancy and a gain from 58 to 65 per cent in the number registering before the seventh month.

About 94 per cent of the patients of private physicians in the classes are primiparas, and they of course are exposed to the greatest obstetric risks. About 40 per cent of the patients of clinics are primiparas.[7]

Experience has led to the belief that the first consideration in any program for the reduction of maternal

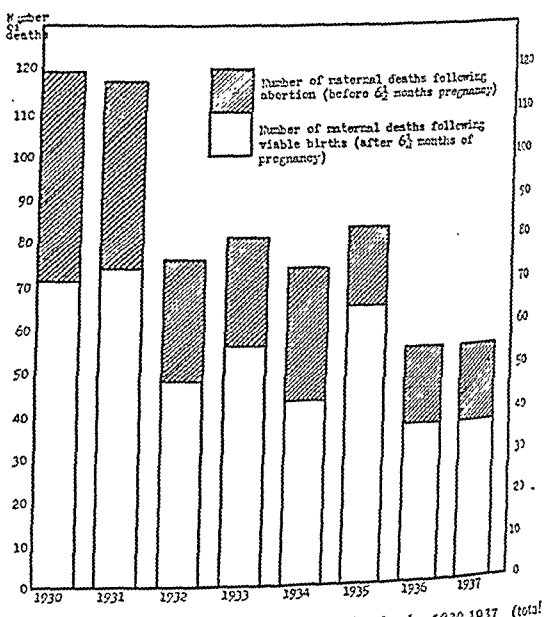

Chart 5.—Number of maternal deaths, Cleveland, *1930-1937* (total deaths, obstetric deaths and deaths due to abortion).

mortality is the puerperal woman herself. Her ability to choose a skilful physician, a competent nurse and a well conditioned hospital are of vital importance. Her capacity to grasp and to carry out simple hygienic rules and her teachability as to the importance of symptoms and signs which indicate approaching danger are large factors. Group instruction in antepartum care, given

6. Prenatal Classes Approved, Bull. Acad. Med. Cleveland **19**: 7 (April) 1935.

7. Evaluation of the Prenatal Group Instruction Program in Cleveland, Ohio (mimeographed), Cleveland, Cleveland Child Health Association, 1938.

by competent public health nurses under the direction of a physician, is proving a successful method of reaching and teaching these essentials to the expectant mother.

When one segregates the women who attended the antepartum classes in Cleveland from the total number of women confined in the city, one finds that the maternal mortality rate in 1933 for the former group was 2 8 deaths per thousand live plus still births and for the women not attending the classes was 5.9. In 1937 the rate for the 2,524 women from the antepartum classes who were confined was only 0.78, as compared with a rate for those not attending the classes of 4.2 deaths per thousand live plus still births (chart 1).

A factor of equal if not greater importance is the type of physician selected to conduct the woman safely through her pregnancy. So long as there are physicians who have been poorly trained and who are making midwifery only a small part of their general medical care. *Failure of proper lay cooperation is responsible for about 50 per cent of the preventable deaths among mothers"* (italics by author).

Comparison of statistics in the 1931 Cleveland study with recent figures furnished by the Academy of Medicine reveal that there has been a trend in Cleveland away from the general practitioner who handles few cases to the physician with a large obstetric practice and to the obstetrician.

The next important factor in the prevention of maternal mortality is the well equipped and properly staffed maternity hospital or maternity division of the general hospital, competently administered under safeguards such as those laid down by the Ohio Hospital Obstetric Society.[3] Studies in Cleveland clearly indicate that the improvements in hospital facilities, in better coordination of visiting and courtesy staffs and in the setting up of high obstetric standards have accompanied the reduction in maternal mortality. One general hospital, which was formerly in Cleveland, has moved to

practice, thus having too few deliveries each year to give them experience in handling the more difficult and complicated ones, there will continue to be high rates. So long as the impression is given that a woman will receive adequate and skilful attention from any physician, just so long will there be complications. It is obvious that physicians having only ten or fifteen obstetric patients a year and hospitals in which less than 150 obstetric patients are confined each year cannot give all the detailed and skilful attention necessary in obstetric practice, especially to patients in whom complications develop.

Dr. Fred Adair[8] and his colleagues have pointed out recently the principles of management of some of the more serious complications of pregnancy. A study of these complications impresses one with the fact that had the women been in the hands of competent obstetricians from the earliest possible date in their pregnancies a considerable number of the complications would not have occurred and the maternal death rate would have been materially lowered. Dr. Adair stated that "women must be properly instructed in personal care and must be taught to cooperate with and appreciate the doctor who is trying to give good antepartum and delivery

East Cleveland and developed a large obstetric division. There has been a trend toward more confinements in the larger, better equipped hospitals.

As a result several smaller hospitals have gone out of business or ceased to take obstetric patients. In 1931, 60 per cent of all registered births in Cleveland occurred in hospitals, while in 1937 the percentage had increased to almost 80 (table 3).

However, one must not lose sight of the fact that the mortality for normal obstetric patients delivered in their own homes by well qualified and experienced physicians remains remarkably low. The experience of the outpatient delivery service of Maternity Hospital in Cleveland reveals a similar low mortality for the patients delivered at home. A hospital may be the safest or the most dangerous place to have a baby, depending on the conditions mentioned. This does not militate against the organization of obstetric services in hospitals, as it is well known that the patients with difficult and complicated labor and a large proportion of primiparas are referred from home service into hospitals.

The physical and mental condition of the prospective mother has roots which reach back into early life and which are conditioned by heredity, disease affecting the bony system, especially of the pelvis, and disease affecting the circulatory, respiratory or endocrine sys-

[8] Adair, F. L.: Maternal Care Complications, Chicago, University of Chicago Press, 1938, p 74

tems. It is evident that a woman coming into pregnancy with a damaged heart or kidneys, with chronic tuberculosis or with a toxic thyroid will be a poor risk regardless of the medical, nursing and hospital attention given to her. Furthermore, a woman with a contracted pelvis due to rickets or achondroplasia already presents complications which may have to be dealt with operatively, and it is known that operative procedures increase risks. Therefore public health measures which reduce any of these hazards will add to the safety of the puerperal woman.

Another practical consideration in the obstetric situation is the financial ability of the family to meet the expenses for the physician and nurse for the confinement and for hospital care when that is desirable or essential. In Cleveland prospective mothers of the upper economic levels have been able to secure proper instruction in maternal hygiene and skilful medical, nursing and hospital attention. This group on the whole has the lowest birth rate and the lowest maternal mortality. Those in the lower economic levels and those on relief have been able to secure good obstetric service

TABLE 5.—*Puerperal Death Rates per Thousand Live Plus Still Births Cleveland, 1930-1937*

Year	Live Births	Still Births	Total Births	Total Puerperal Deaths	Rate
1930	17,895	705	18,600	119	6.4
1931	16,279	597	16,876	117	6.9

1937	37	2.3	18	1.1	5.5

through the Maternity Hospital outpatient department and through the maternity service at City Hospital.

On the other hand, a considerable number of prospective mothers in the middle class have found it extremely difficult to meet the expenses of a pregnancy. It is for this group, in which the husbands or the women themselves are employed as workers in shops, factories or stores, that the Hospital Service Association's provision for hospitalization of parturient women is a great boon. More than 155,000 persons are insured in the association plan, which allows twenty-one days of hospital care a year in one of sixteen approved Cleveland hospitals for a monthly premium of from 60 to 75 cents. April 1, 1938, the service was extended to include confinements for those participating in the plan for more than a year. In October the service was extended further to include the entire family. I am confident that in a few years, when full advantage is taken of these provisions, there will be a still further reduction in the maternal mortality rate in Cleveland. There will be greater improvement in technic in hospitals taking obstetric patients under the plan and a more judicious selection of obstetricians by the patients, who will plan early in pregnancy for confinement in one of these hospitals.

Unless the prospective mother can be impressed with the importance of an early choice of a skilful and conscientious physician and it is made possible for her to choose a physician from among the most competent obstetricians in the community, and unless it is made possible for those in the lower economic levels to obtain adequate medical, nursing and hospital care, a material reduction in maternal mortality rates cannot be expected. There may be adequate hospital facilities, a large enough number of physicians and obstetricians in the community and all the necessary nursing facilities, yet, if these cannot be brought to bear directly on the prospective mother at every economic level, other efforts will prove fruitless. The maternal mortality rate will be reduced only in proportion to the community organization which assures the coordination of all these forces.

Accurate reporting of births and deaths is essential to any appraisal and comparison of mortality rates. It must be recognized that a comparison of the rates of one city with those of another and with state and national statistics requires careful interpretation. In the state department of health a reclassification of data submitted by cities may take place because of differences in interpretations and the system of tabulation. By actual comparison it was found that the official rates submitted by cities differed slightly from those furnished by the United States Bureau of the Census in practically all instances. In a comparison of the maternal mortality rates in cities over a period of years, the official rates as issued by the Bureau of the Census are the only ones that are comparable.

Since the adoption of the "1929 International Classification of Causes of Death" by the Cleveland Bureau of Vital Statistics (in 1931) it has been possible to secure the segregation of abortions accompanied with septic conditions from abortions without mention of septic conditions. Other improvements have been made in that classification, but it still does not cover all the points necessary to a complete evaluation of the preventability of maternal deaths. However, the Cleveland Bureau of Vital Statistics has made marked strides in the direction of securing completeness of registration of puerperal deaths, especially in the hospitals, through the cooperation of the Hospital Obstetric Society, and also has checked all cases of obscure causation, so that today the picture from official sources is much more reliable than it was prior to 1931 (table 4).

With the demographic studies of Howard Whipple Green[9] in connection with economic areas in census tracts, one is able to evaluate socio-economic factors entering into the problems of maternal and infant mortality. The data all lend greater reliability to the Cleveland figures for the past eight years and make a comparison of trends more reliable.

The birth rate has varied but little in Cleveland since 1933. The character of the population has remained about the same, although there have been fluctuations in the number on direct and on work relief. There have been no serious epidemics that might have affected the maternal mortality.

As a result of the studies made of maternal mortality, it may be stated that there was no demonstrable downward trend in the official puerperal mortality rate in Cleveland from 1910 to 1931, the yearly rate fluctuating irregularly between 4.3 and 7.2 deaths per thousand live births. From 1931 to 1938 there was a decided downward trend in the maternal mortality rate, with minor yearly fluctuations, from 7.2 in 1931 to

9 Green, Howard W.: Demographical Data, Cleveland, Ohio, 1911 to 1937, Cleveland, Cleveland Health Council, 1938

3.7 in 1937 and 2.9 for the first seven months of 1938. One may reasonably compare the rates since 1930, and especially since 1933 (table 1), because it is known that the registration of births and deaths has become more complete, that the classification of causes of death has become more exact and that more detailed studies of hospital deaths have taken place (table 4).

If the classification of the Cleveland Hospital Obstetric Society is adopted, the favorable change in rates is brought out even more clearly. In 1931 the rate per thousand live plus still births for patients more than six and one-half months pregnant was 4.4, while the rate for those dying before they were six and one-half months pregnant, this figure, including all deaths registered as due to abortion, was 2.5. In 1937 these rates had dropped to 2.3 and 1.3 (table 5 and chart 5).

The answer then to the question as to whether there has been an actual reduction of maternal mortality in Cleveland is Yes. It remains to state that maternal mortality rates in other large cities have been falling to new lows. There has been a general decline in the maternal mortality rates throughout the country. It would be valuable to have the experiences of other cities analyzed and presented to the American Public Health Association.

FACTORS ASSOCIATED WITH FETAL AND NEONATAL DEATHS

ANALYSIS OF 773 SUCH DEATHS OCCURRING IN 17,728 DELIVERIES AT THE CHICAGO LYING-IN HOSPITAL

EDITH L. POTTER, M.D.
AND
FRED L. ADAIR, M.D.
CHICAGO

In the past few years there has been an increasing recognition of the need for further investigation of the factors associated with death of the fetus in utero and during delivery and of the infant in the first few days of life. Attention for some time has been focused on the older infant, with the result that deaths occurring in the period from the end of the first month to the end of the first year of life have been greatly reduced (100 per thousand live births in 1915 to 56 per thousand live births in 1935). The death rate in the first month has shown little reduction, while the rate for the first day of life and for stillbirths has remained practically stationary during the entire period since vital statistics on the subject have been collected.

Except for disorders arising from defects of the germ plasm, the welfare of the fetus and of the infant in the period immediately following delivery is largely dependent on the condition of the mother during pregnancy and on the character of labor. It is not until an independent existence has been completely established that pathologic conditions intrinsic in the infant become important lethal factors. The physician therefore must attempt to eliminate any maternal condition which might adversely affect the fetus during the prenatal period and ameliorate any harmful processes occurring during labor if the morbidity and mortality rates are to be decreased.

From the Department of Obstetrics and Gynecology, the University of Chicago and the Chicago Lying-in Hospital.

It is believed that an analysis of conditions associated with fetal and neonatal death in a large series of deliveries in which the maternal complications and obstetric procedures employed are known, not only in those which die but also in those which survive, might enable one properly to evaluate the factors responsible for fetal and infant deaths.

Considerable difficulty is encountered in attempting to group causes of fetal death, and many classifications heretofore published consist of a mixture of fetal and maternal states. Craniotomy (unless performed on a live fetus), maceration, atelectasis and prematurity in stillborn fetuses are not causes of death and should not be listed as such. No single classification of pathologic conditions gives sufficient information with regard to the fundamental factors responsible for death, and it is only by multiple tables that adequate information can be obtained. In attempting to evaluate the various factors associated with fetal and infant mortality, it is important to know the pathologic conditions present in the fetus or infant, the effect that abnormal maternal conditions present before labor have on the fetus or infant, the effect of different types of labor and delivery on the fetus or infant, and the relation of maternal complications, type of delivery and cause of death to the period of gestation at which the fetus or infant is delivered. The causes of death will be presented from each of these points of view.

GENERAL PROCEDURE

The criteria used to determine the age of a fetus or infant are based on Scammon's figures for weight and length in relation to the menstrual age of the fetus. The fetus is placed in the group in which at least two of the three criteria apply.

I. Abortion:
   1. Less than 400 Gm. in weight.
   2. Less than 28 cm. in length.
   3. Less than 22 weeks (missed abortions are excluded).

II. Premature:
   A. Previable:
      1. From 400 to 999 Gm. in weight.
      2. From 28 cm. to 35 cm. in length.
      3. From the 22d to the end of the 28th week.
   B. Viable:
      1. From 1,000 to 2,499 Gm. in weight.
      2. From 35.1 cm. to 47 cm. in length.
      3. From the 29th to the end of the 37th week.

III. Term:
   1. From 2,500 to 4,499 Gm. in weight.
   2. From 47.1 cm. to 54 cm. in length.
   3. From the 38th to the end of the 42d week.

IV. Postmature:
   1. More than 4,500 Gm. in weight.
   2. More than 54 cm. in length.
   3. More than 42 weeks.

The law in the state of Illinois requires that the birth of all live infants and of stillborn fetuses which have advanced to the fifth calendar month of gestation be recorded. Therefore the birth of infants delivered between the fifth month and the period of viability (end of the seventh month) must be recorded, and these deaths must be included in the computation of mortality statistics even though there is no chance of a continued existence. Infants at the end of the seventh month weigh about 1,000 Gm. Many hospitals accept 1,500 Gm. as the lower limit of viability and disregard in statistical reports all infants below this weight. Dunham and her associates, however, found

in a study of more than 5,000 premature infants that, although 98.8 per cent of all infants weighing less than 1,000 Gm. at birth failed to survive, 35 per cent of those between 1,000 and 1,500 Gm. did survive. The deletion of this group of infants from statistical records cannot be justified on the ground that they are previable.

The product of conception is considered stillborn if it shows no sign of life at birth (heart beat, respiration, muscular movement)[1] and live born if the heart is beating when born, even though respiration is never established.

Autopsies have been performed on 68 per cent of the fetuses and infants delivered and dying in the Chicago Lying-in Hospital. Only too frequently autopsy fails to reveal the cause of death, but despite this, postmortem examination of the infant is as important in determining the absence of pathologic conditions as it is in establishing their presence. The maternal history is an extremely important adjunct to the autopsy protocol, and any statement as to the cause of death based on the summation of knowledge contained in a complete maternal history plus an accurate autopsy protocol is of inestimably more value than an opinion based on one alone.

An attempt has been made to group together closely related pathologic conditions in order to simplify the discussion. Most lesions sufficient to cause death fall into five major groups. They are (1) hemorrhage, either visceral or intracranial, usually caused by trauma, (2) anoxemia, (3) malformations, (4) infections and (5) idiopathic conditions. There are ordinarily no pathologic changes demonstrable in premature infants who die because of insufficient development. In the case of an infant delivered in the previable or viable premature period, prematurity is not given as a cause of death in the absence of pathologic changes, but the fact that it was born in the previable or viable premature period and that no pathologic lesions were found is stated.

Intracranial hemorrhage includes only those cases in which there was definite bleeding into the brain substance or cranial cavity. This bleeding is often associated with laceration of the supporting stuctures and in most cases is due to actual trauma. When there was slight extravasation of cells into the leptomeninges of the type so commonly seen in association with the extreme congestion produced by anoxemia, the infant was placed in the group dying from anoxemia and not with those having intracranial hemorrhage.

Anoxemia is considered the cause of death only when definite petechial hemorrhages are visible in the lungs, heart, thymus or meninges. Petechial hemorrhages when present in one organ are often present in all organs. They are most characteristic in association with death from premature separation of the placenta but usually occur in any obstruction of circulation through the cord or placenta. When death is due to anoxemia, epithelial cells and vernix caseosa derived from the amniotic fluid are demonstrable microscopically in the alveoli of the lungs in much larger quantities than when death occurs from other causes.

Malformations include only those defects which are in themselves capable of causing death. Even though there may have been coincidental maternal complications the malformation is given precedence as a cause of death over any maternal condition. Erythroblastosis has been included under this heading, since we believe that it is most probably a congenital maldevelopment of the hemopoietic system.

Infections are an extremely infrequent cause of death and in general are listed individually. Syphilis and pneumonia are the two most commonly encountered, and even these are rare.

Idiopathic conditions may include hemorrhagic disease of the newborn, glycogen storage disease (von Gierke's disease), hypoglycemia unrelated to maternal diabetes, edema of the brain and the like. Except for one case of hemorrhagic disease, edema of the brain was the only one of these conditions found in the present series. It occurred nine times and most frequently followed birth by cesarean section. Most of the infants died with clinical symptoms indicating increased intracranial pressure. It is not known whether death is due to increased fluid, but it seems wise to place these cases in a separate group since they showed no other pathologic changes.

Atelectasis (lack of expansion of the alveoli) has in no case been considered a cause of death. We believe that atelectasis is not the cause but the result of the processes which produce the death of the infant. It would be advantageous if a term could be introduced which would differentiate the atelectasis due to primary nonexpansion of alveoli and secondary collapse of alveoli due to resorption of air. The first is the type most commonly seen in newborn infants; the second is most often found after the first few days of life. Expansion of alveoli is a gradual process, and lungs of infants a few hours old normally contain less air than those several days old. Abnormal lack of expansion may be due to depression of the respiratory center (anoxemia, trauma, narcotics from the maternal circulation, cerebral malformations), local compression of the lungs (diaphragmatic hernia, polycystic kidneys, pleural effusion) or immaturity of the respiratory center, lungs and thoracic muscles. In none of these conditions is the unexpanded condition of the lungs the actual cause of death.

The role that analgesia and anesthesia play in producing fetal or infant death is extremely difficult to determine. The respiratory center of the infant may become so depressed by excessive or ill timed administration during labor that its function is inhibited and respiration sufficiently delayed to cause death. However, no pathologic lesions are ordinarily produced in the infant's body and it is usually impossible to prove that this was the actual cause of death.

GENERAL ANALYSIS

Since the opening of the new physical plant in May 1931 until Jan. 1, 1938, 17,728 infants have been delivered at the Chicago Lying-in Hospital. Of these 402 were stillborn and 371 died either before discharge from the hospital, or within ten days after birth. This is a total death rate of 21 per thousand live births and a stillbirth rate of 23 per thousand live births.

General Mortality in Relation to Age at Birth.—Among the total infants and fetuses delivered, the great majority (93.3 per cent) remained in utero a normal length of time, and only a small portion (5.8 per cent) were delivered during the viable premature period. Less than 1 per cent (0.5 per cent) additional were previable. The mortality for infants and fetuses at term is only 1.9 per cent, but for those born prematurely it is increased eighteen fold (34.6 per cent) and practically none born in the previable period survive (98.8 per cent).

1. Throughout this paper the term fetus is used to indicate a product of conception born dead at any period of gestation.

Among the infants born alive 94.4 per cent were at term, 5.3 per cent were viable premature infants and 0.3 per cent were previable. The mortality rate for infants at term is 0.8 per cent, for viable premature infants 18.1 per cent, for previable infants 96 per cent. Thus the term infant has twenty-one times more chance of surviving than does the premature infant.

A relatively greater proportion of the stillborn fetuses reached term before delivery (47.1 per cent) than did those infants who died in the neonatal period (35.8 per cent). The opposite is true in the viable premature period, for 42.2 per cent of the stillborn fetuses and 50.9 per cent of the infants dying neonatally fall in this group.

Although of all infants and fetuses delivered only 5.8 per cent were viable premature infants and 0.52 per cent were previable, there were more deaths in these two groups combined than there were among all those who were delivered at term. Only 41.6 per cent of the total deaths were in infants and fetuses at term, while 46.5 per cent occurred among those delivered during the viable premature period and 11.9 per cent were in those delivered during the previable period.

Time of Death in Relation to Labor in Stillborn Fetuses.—Death occurred before the onset of labor in half (50 per cent) of all stillborn fetuses and during labor in more than one third (35 per cent); the time of death was unknown or not recorded in 15 per cent. Sixty-two per cent of the fetuses that died during labor were at term in comparison to 39 per cent of those that died before the onset of labor. The actual number of term fetuses dying during labor is almost twice that of premature fetuses dying during labor. However, death occurred during labor in 5.1 per cent of the infants and fetuses delivered prematurely who were known to be alive at the onset of labor and in only 0.47 per cent of the infants and fetuses delivered at term. Thus the premature fetus has 10.8 times more likelihood of dying during labor than does the fetus at term.

Extra-Uterine Age at Death.—Of the 371 infants who died after birth, eighty-seven lived less than one hour (in the majority of these normal respiration was never established), 192 lived more than one but less than twenty-four hours and eighty-one lived from one to ten days, while eleven died after ten days. A total of 279, or 75.2 per cent, died within the first twenty-four hours of life. This indicates that some process intimately associated with intra-uterine life, the process of birth or the establishment of an extra-uterine existence was directly responsible for at least three fourths of all deaths.

Type of Delivery in Relation to Total Births.—Among the total infants and fetuses almost two thirds (61.7 per cent) were delivered in a cephalic position without operative procedures other than episiotomy. More than one fourth (27 per cent) were delivered in a cephalic position with the aid of forceps (low forceps in 22.4 per cent, mid forceps in 4.6 per cent). The breech was the presenting part in 4 per cent of all deliveries; cesarean section was the method of delivery in 5.8 per cent, and podalic version with subsequent extraction was performed in 0.9 per cent of all cases.

TYPE OF DELIVERY IN RELATION TO FETAL AND NEONATAL MORTALITY

The gross neonatal mortality (0.89 per cent) is less for cephalic deliveries aided by low forceps than for any other type of delivery. The next lowest figure is for infants delivered naturally in a cephalic position (1.5 per cent). Other operative procedures are associated with progressively greater mortality; mid and high forceps 2.4 per cent, cesarean section 6 per cent, breech delivery 7.9 per cent, version and extraction 12.9 per cent.

The stillbirth rates follow the same general order of increase in relation to the type of delivery as do the neonatal death rates. In general, except in delivery by version and extraction and by cesarean section there are about an equal number of neonatal deaths and stillbirths in each group. Associated with cesarean sections there are only half as many stillbirths (thirty-one) as there are neonatal deaths (sixty-two), owing largely to the fact that unless the mother's life is at stake sections are not performed when the fetus is dead. The stillbirths (thirty-five) are 50 per cent higher than the neonatal deaths (twenty-three) when delivery is by version and extraction.

Correction of Figures for Conditions Which Are Not Affected by Type of Delivery.—The gross figures appear to indicate that delivery by low forceps has a considerably lower rate than any other type. However, since the delivery itself can have no effect on deaths occurring before the onset of labor, on those due to major malformations or on those resulting from delivery of the fetus before the period of viability, the deletion of these from the total deaths with recalculation of the rates gives much more accurate information regarding the effect of delivery (table 1). The mortality rate (neonatal deaths and stillbirths combined) thus calculated for natural cephalic delivery (1 per cent) is only one third of its gross rate and is slightly lower than delivery by low forceps (1.1 per cent). Although the total rate in each type of delivery is lowered, in each it is lowered proportionately less than in spontaneous cephalic deliveries, so that in relation to this type of delivery other methods have a greater hazard than is indicated by the gross figures.

TABLE 1.—*Corrected Mortality Rates*

	Gross Mortality, per Cent	Corrected Mortality, per Cent*	Corrected Mortality, per Cent, Adjusted to 5 per Cent Prematurity†
Total deliveries	4.4	2.5	2.5
Natural cephalic deliveries	3.0	1.0	1.1
Low forceps	1.4	1.1	1.3
Mid and high forceps	5.0	4.2	5.0
Breech deliveries	16.5	9.7	7.1
Cesarean section	8.9	6.5	4.1
Version and extraction	34.5	22.3	13.4

* Deletion of all infants and fetuses dying before the onset of labor, before the period of viability or from malformations.

† 0.05 times the death rate for prematures in each type of delivery plus 0.95 times the death rate for term infants in each type of delivery.

Even after these calculations are made there still remain the variations in the number of premature births in each group as factors affecting the death rates. The mortality rate for premature fetuses and infants is approximately eighteen times that of those at term, so that a large number of premature infants in any one group makes the figures for that type of delivery disproportionately high. Since among the live born infants delivered in the hospital 5 per cent are premature, adjustment of the number in each type of delivery to 5 per cent eliminates prematurity as a factor causing variation in the death rates. After the previable, malformed and those dead before the onset of labor have

been eliminated and the adjustment made for prematurity, the corrected rate is slightly raised for natural cephalic (1.1 per cent), low forceps (1.3 per cent) and mid forceps (5 per cent) deliveries and lowered for breech (7.1 per cent), cesarean section (4.1 per cent) and version and extraction (13.4 per cent). Thus delivery by low forceps has a slightly higher rate than natural cephalic delivery, while mid forceps is four and one-half times as high, breech six and one-half times, cesarean section a little more than three and one-half times and version and extraction twelve times as high.

Natural Cephalic Delivery.—Of the 10,877 infants and fetuses born by natural cephalic delivery, 1.5 per cent were stillborn and 1.5 per cent died in the neonatal period. Only one third were at term (term 33 per cent, viable premature 52.4 per cent, previable 14.2 per cent). In each of the age groups there were approximately an equal number of stillbirths and neonatal deaths. Maternal complications were associated with fetal or neonatal death in 57 per cent of the stillborn and in 32 per cent of the live born infants. The most common complication was toxemia, which occurred in 27.6 per cent of the mothers of stillborn fetuses and 10 per cent of those infants who died in the neonatal period. Hemorrhage from placenta praevia or premature separation of the placenta occurred with the next greatest frequency and was associated with 15.2 per cent of the stillborn fetuses and 5.7 per cent of the live born infants who died in the neonatal period.

Investigation of the pathologic lesions at autopsy reveals the startling fact that 38.6 per cent of the live born infants and only 10.3 per cent of the stillborn fetuses died as a result of major malformations. If only infants at term are considered, 67 per cent of those live born died of malformations while 14.6 per cent of the stillborn fetuses died of the same cause. Thus in live born infants who are delivered without instrumentation the most important lethal factor is a major malformation.

In addition to malformations, the most common pathologic lesions in infants dying during the neonatal period are intracranial hemorrhage 12 per cent and anoxemia 12 per cent. Ninety-two per cent of the previable infants, 39 per cent of the premature infants and only 4 per cent of the infants at term showed no pathologic changes.

The other conditions found at autopsy in stillborn fetuses were anemia 11.2 per cent, intracranial hemorrhage 1.7 per cent, intra-uterine pneumonia 1.7 per cent and no demonstrable pathologic changes 73.4 per cent. Slightly over half (51.7 per cent) of the fetuses examined at autopsy were macerated.

The majority (85 per cent) of the fetuses born of mothers with no known complications were macerated; they were macerated in slightly less than half of those in which there was an associated toxemia (42.4 per cent) and in only 29 per cent of those associated with placenta praevia or abruptio placentae. This indicates that intra-uterine deaths associated with no known maternal complications usually take place hours or days before delivery; those associated with toxemia occur before the onset of labor and during labor with about equal frequency, while the greatest number of deaths associated with maternal hemorrhage occur only a short time before delivery.

Cephalic Delivery Aided by Forceps.—Among the 3,995 deliveries in which low forceps were used there were 0.55 per cent stillbirths and 0.87 per cent live born infants who died during the neonatal period. Maternal complications were present in association with 52 per cent of the deaths in this group in contrast to 44 per cent in natural cephalic deliveries. Seventy per cent were at term. Causes of death in the thirty-two infants and fetuses examined at autopsy were intracranial hemorrhage 31 per cent, anoxemia 28 per cent, malformations 25 per cent and no abnormalities 16 per cent.

A total of 835 infants and fetuses were delivered by mid or high forceps. Of these 2.6 per cent were stillborn and 2.4 per cent died in the neonatal period. In 45 per cent Duehrssen's incisions were made prior to delivery. There were, in the total group, nine mothers showing toxemia and two with abruptio placentae, and in most of the remainder there was difficulty in delivery, the latter due especially to cervical dystocia. Seventeen per cent of the infants and fetuses were premature, 83 per cent were at term. Thirty-two were examined at autopsy. Sixty-five per cent of these showed evidence of birth trauma, 9 per cent died of major malformations, 13 per cent died of anoxemia and 13 per cent showed no pathologic lesions.

In both groups of infants and fetuses examined at autopsy the main cause of death was birth trauma; it accounted for death in 65 per cent of those delivered by mid forceps, 31 per cent of those delivered by low forceps.

Breech Delivery.—A total of 708 infants and fetuses were delivered in a breech position with a resulting mortality of 7.9 per cent during the neonatal period and an incidence of 8.6 per cent stillbirths.

The causes of death demonstrable at autopsy in infants and fetuses delivered in a breech position were anoxemia 20 per cent, intracranial or intraperitoneal hemorrhage 17.4 per cent, malformations 10.6 per cent and infections 4 per cent. In 48 per cent no anatomic cause of death could be demonstrated; this includes the 20 per cent that were macerated, the 17 per cent that were previable and the 11 per cent that were premature or at term that showed neither maceration nor pathologic lesions. Maternal complications were present before delivery in 32.6 per cent of the women whose infants died or were stillborn; toxemia occurred in 12 per cent, hemorrhage due either to placenta praevia or to premature separation of the placenta in 12 per cent and prolapse of the cord in 10.6 per cent.

Delivery by Cesarean Section.—Among 1,041 cesarean sections there were delivered thirty-one (3 per cent) stillborn fetuses and sixty-two (6 per cent) live born infants who died during the neonatal period. Of the total number of infants and fetuses 36.5 per cent were at term, 50.5 per cent were premature but viable and 13 per cent were previable.

The main indication for cesarean section in the cases in which the fetuses were stillborn was hemorrhage due to premature placental detachment; this was present twenty-two (70 per cent) times; seven of these were associated with toxemia. In six (20 per cent) the indication for section was severe toxemia without premature placental separation, in two (7 per cent) central placenta praevia, in one (3 per cent) brain tumor. Twenty-two of the fetuses were examined at autopsy. Fifty-five per cent showed the petechial hemorrhages characteristic of interference with circulation, and in 9 per cent there was intracranial hemorrhage. In 36 per cent there were no pathologic lesions; of these, 23 per cent were so macerated that petechial hemorrhages could not have been identified even if originally present.

The indications for cesarean section in the sixty-two live born infants who subsequently died were toxemia 35.4 per cent, hemorrhage 30.6 per cent (placenta praevia nine, abruptio placentae ten), medical complications 19.5 per cent (heart disease nine, tuberculosis one, diabetes one, epilepsy one), small pelvis 11 per cent (first section two, with previous section five), necrotic fibroid one (1.6 per cent), previous antepartum fetal death one (1.6 per cent).

Forty-four of these infants were examined at autopsy. twenty-seven per cent of these showed no pathologic lesions (six were viable premature infants, three previable infants). Twenty-one per cent (three term, six premature) had marked edema of the brain without other demonstrable abnormality, 19 per cent had petechial hemorrhages, 16 per cent showed intracranial hemorrhage (three term, four premature), 10 per cent had major malformations, 7 per cent had pneumonia. It is interesting to note that six of the seven cases showing intracranial hemorrhage were cases in which the indication for section was toxemia.

The total 1,041 cesarean sections have been analyzed according to the indications for which they were performed. In considerably over half (60.1 per cent) the indication was disproportion, dystocia or previous cesarean section. The infants were stillborn or died in the neonatal period in only 1.1 per cent of these cases. Hemorrhage from premature separation of the normally implanted placenta or placenta praevia was the indication in 12.5 per cent, with fetal or neonatal deaths occurring in 33.6 per cent. Toxemia (in most instances due to chronic renal impairment) was the indication in 12.3 per cent; the infants were stillborn or died in the neonatal period in 22.7 per cent of this group. The remaining 15.1 per cent of the sections were performed because of cardiac insufficiency or other local or systemic conditions; 10 per cent of these infants were stillborn or died in the neonatal period.

Thus, although the indication was hemorrhage or toxemia in only 25 per cent of the total cesarean sections, in 76 per cent of the sections in which the fetus or infant succumbed this was the indication present. When cesarean section is performed in the absence of maternal complications which may involve the fetus, the mortality rate is low.

Delivery by Version and Extraction.—A total of 162 infants and fetuses were delivered by version and extraction; 20.3 per cent were stillborn and 14.1 per cent died in the neonatal period. Forty-three per cent were at term, 53.5 per cent were premature but viable and 3.5 per cent were previable.

The principal indication for version and extraction which was followed by death of the fetus or infant was hemorrhage associated with placenta praevia or premature placental separation. This was present twenty-eight times, or in approximately half of the cases. Malposition (ten) or long labor (two) occurred in about one fifth of the cases, while prolapsed cord (four), failed forceps (four), hydramnios (three), toxemia (two), second twin (one) and unstated (two) made up the remainder. Toxemia was present in eight cases in addition to the two in which it is given as the indication for version (malposition two, placenta praevia one, placental separation two, failed forceps one, prolapsed cord two).

In seven cases the Braxton Hicks was the type of version performed. In fifteen (26 per cent) a bag induction preceded the version.

Thirty-seven of the total fifty-six dead infants and fetuses were examined at autopsy. The cause of death was anoxemia in 50 per cent, malformations in 19 per cent, intracranial hemorrhage in 13.5 per cent, pneumonia in 2.7 per cent and undetermined in 16 per cent.

Version and extraction carries the highest fetal and infant mortality of any operative procedure. From an analysis of the cases, however, it becomes evident that the high rate is due to the type of case in which this procedure is instituted rather than to the delivery itself. Death in the five infants showing evidence of intracranial injury may probably be attributed to the type of delivery, but the majority of the 50 per cent of deaths from anoxemia were due to maternal hemorrhage or interference with circulation through the cord. The 19 per cent due to major malformations cannot be attributed to the type of delivery.

Delivery by Craniotomy.—Among the fifty-eight infants delivered by craniotomy, thirty-four died before the onset of labor and twenty-four during labor. Twenty of the thirty-four dying before the onset of labor were macerated. There are no outstanding causes of death as shown by autopsy or maternal complications. In about one fourth there were no known maternal complications or demonstrable abnormalities in the infants or fetuses. Nine were associated with maternal toxemia, eight with placenta praevia or premature placental separation, eight were malformed infants (none of whom were born of mothers with complications), eight were associated with cord knots, prolapse, entanglements and the like. In eleven there was a history of long labor or difficult delivery, and two of these infants showed evidence of intra-uterine pneumonia. There were also no great differences in causes of antepartum and intrapartum deaths except in the number of deaths occurring without maternal complications (excluding the malformations). Of these there were eleven cases in the antepartum period and only two in the intrapartum period.

MATERNAL COMPLICATIONS

Maternal Complications in Relation to Pathologic Conditions in the Infant and Fetus.—In 44.6 per cent (354) of the 773 fatalities in this series maternal complications including premature placental separation, placenta praevia, toxemia, cord entanglements or prolapse, medical complications (heart disease, diabetes, pyelitis and the like) or syphilis were present. In only 31.6 per cent, however, could the complication be considered as the probable cause of death, for in the other 13 per cent definite pathologic lesions such as intracranial hemorrhage, malformations and infections were present. In those cases in which the only pathologic lesions demonstrable were petechial hemorrhages, death was believed probably due to the maternal complications and they are included in the 32 per cent so designated.

Hemorrhage from premature placental separation or placenta praevia was the most common complication and was found in 117 cases (33 per cent). In almost half (43 per cent) of these infants and fetuses there were no pathologic lesions. In over one third (38 per cent) petechial hemorrhages were present, and in the remaining 17 per cent a variety of causes of death were found.

Among the infants born of toxemic mothers (114) only 18 per cent showed definite evidence of anoxemia (petechial hemorrhages) and 21 per cent showed other pathologic lesions, while in 61 per cent no evidence of

a cause of death could be found. It is very probable that toxemia was the main inciting factor in the majority of the first and last groups.

In an additional twenty-eight cases both toxemia and premature placental separation were present. Seventeen of these infants and fetuses had petechial hemorrhages in the thoracic viscera; in eleven there were no abnormalities.

Cord abnormalities producing interference with circulation (fifty-four) were less than half as common as either toxemia or hemorrhage. As would be expected, the most common abnormalities in these infants were those indicative of anoxemia (42 per cent). In 13 per cent there was intracranial hemorrhage or a major malformation, and in 44 per cent no pathologic changes were present. In one third of the last group maternal hemorrhage or toxemia also was present.

Absence of Maternal Complications.—There were no maternal complications associated with the death of 419 (55 per cent) fetuses and infants. Of these, 175 (22.6 per cent of all deaths) showed pathologic changes at autopsy or a fairly definite cause of death was assigned clinically. In 244 (30.2 per cent) there was neither a maternal complication nor a demonstrable cause of death. In the different age groups, absence of maternal complications and pathologic lesions occurred with the following frequency: (*a*) deaths in the neonatal period; term, 8.2 per cent, premature, 29.1 per cent, previable, 63 per cent; (*b*) stillborn; term, 20.6 per cent, premature, 20.6 per cent, previable 47.8 per cent.

There were only thirteen women in whom a history of a syphilitic infection was obtained. Only four of nine infants or fetuses examined at autopsy showed evidence of syphilis; in the three not examined there was no clinical evidence of syphilis. The total incidence of maternal syphilis in this series is only 1.3 per cent. It is probable that not more than half this number actually died of syphilis.

Maternal Complications in Relation to Time of Death.—The lowest incidence of maternal complications is found in term infants who die in the neonatal period (9 per cent). In stillborn term fetuses the incidence of complications in the mother is three times as great (28 per cent). They are most common in association with the birth of dead premature or previable fetuses (37 per cent), while they occur in 26 per cent of premature or previable infants who died in the neonatal period.

CAUSE OF DEATH AS DEMONSTRATED BY AUTOPSY

Incidence of Pathologic Lesions in Relation to Time of Death (table 3).—Sixty-eight per cent (526) of all dead infants and fetuses born in the Chicago Lying-in Hospital during the period under investigation were examined at autopsy; this comprised 66 per cent of the live born infants and 70 per cent of the stillborn fetuses. The number of live born (48 per cent) and the number of stillborn (52 per cent) were almost equal, and the number falling into the previable, premature and term groups were remarkably evenly divided between those stillborn and those which were live born. Of the entire group 12.2 per cent were previable, 14.1 per cent were premature and 43.7 per cent were at term.

It was impossible to demonstrate pathologic changes in 52 per cent of the stillborn fetuses and in 32 per cent of the live born infants. However, in only eleven term infants and fetuses was there absence of pathologic lesions. Only 5 per cent of live born infants in whom

no pathologic lesions were present were at term, so that in the remaining 27 per cent prematurity was the probable cause of death.

In ninety-seven of the 148 stillborn fetuses in whom no pathologic lesions were demonstrable, maceration had advanced to a degree sufficient to have masked any hemorrhage which might have been present; there were only 18 per cent of the fetuses which showed neither maceration nor pathologic changes.

In the combined series of stillbirths and neonatal deaths anoxemia (18.5 per cent) and malformations (18.1 per cent) are the most important lethal factors, and an almost equal number of deaths fall in each group. However, the distribution is decidedly different in the two groups, for there are twice as many malformations as anoxemias in the live born group and twice as many anoxemias as malformations among those who were stillborn. Thus malformations are the most common cause of death in live born infants (24.5 per cent), while anoxemia is the most common cause in stillborn fetuses (23.8 per cent). Anoxemia accounts for 12.2 per cent of the deaths in live born infants, malformations for 12.4 per cent of the deaths in stillborn fetuses.

definitely known, and whether or not it is a lethal factor cannot be stated positively. It was found most frequently following birth by cesarean section; the majority of the infants lived from eight to twenty-four hours and showed clinical evidence of increased intracranial pressure.

Erythroblastosis was present in four live born infants and in six stillborn fetuses, an incidence of 1.3 per cent of the total deaths. These cases were included with those presenting malformations because the conditions seem most probably due to a congenital malformation of blood-forming tissue.

Only one case of hemorrhagic disease of the newborn was present in the entire series. This case was included under visceral hemorrhage.

Pathologic Changes in Relation to Type of Delivery.—In autopsies performed on viable infants and fetuses malformations account for 5 per cent of the deaths of those delivered by cesarean section, 7 per cent of those by high or mid forceps, 9.2 per cent of those by version and extraction, 9.3 per cent of those by breech delivery, 14 per cent of those by low forceps and 20 per cent by natural cephalic delivery. It is interesting to note

TABLE 3.—*Causes of Death as Demonstrated at Autopsy of 526 Fetuses and Infants*

	Hemorrhage		Anoxemia		Malformations		Infections		Miscellaneous		Undetermined		Total

Total	83	15.8	97	18.5	95	18.1	16	2.9	9	1.7	226	43.0	526	100.0

The third most frequent cause in the combined series is gross hemorrhage, usually intracranial and usually traumatic. It is present in 15.8 per cent of the entire group but is more than twice as frequent in live born infants as in stillborn fetuses. It accounts for 23.4 per cent of the deaths in live born infants (second in importance) and for 9.3 per cent of the stillbirths (third in importance).

Infections are much less frequent than the three preceding factors and caused death in only 3 per cent of the cases. They are twice as common in live born infants as in stillborn fetuses. The types of infections were pneumonia nine (those having both intracranial hemorrhage and pneumonia were placed with the former group), syphilis four, septicemia two and diphtheria one.

The incidence of syphilis seems remarkably low, but in addition to the four cases of proved syphilis there were only five other infants examined at autopsy who had been born of mothers with a positive Wassermann reaction, and syphilis could not be demonstrated in those infants. The total of nine cases, four proved and five in which it may possibly have been a contributing factor, represents only 1.3 per cent of all the infants and fetuses examined at autopsy.

Edema of the brain without other pathologic changes was present in 1.7 per cent of all autopsies but was found only in live born infants. Its significance is not

that this is almost the reverse order of importance of intracranial hemorrhage as a cause of death.

Anoxemia accounts for 8.1 per cent of the cases in which autopsies were performed on viable infants and fetuses delivered naturally in a cephalic position, 9.3 per cent by high or mid forceps, 15.7 per cent by low forceps, 17.6 per cent by breech, 23.4 per cent by cesarean section and 33.4 per cent by version and extraction.

Intracranial hemorrhage accounts for 6.1 per cent of the deaths among autopsies performed on viable infants and fetuses delivered naturally in a cephalic position, 9.2 per cent by version and extraction, 9.6 per cent by cesarean section, 17.5 per cent by low forceps, 21.1 per cent by breech deliveries and 46.8 per cent by high or mid forceps.

Of the three most important causes of death, anoxemia shows the highest incidence in version and extraction and in cesarean section; malformations in natural cephalic deliveries and in those aided by low forceps; intracranial hemorrhage in high forceps and in breech deliveries.

Pathologic Lesions in Relation to Degree of Maturity.—Anoxemia occurs as a cause of death with fairly equal frequency in the total number of autopsies on infants and fetuses at term (19 per cent) and those in the premature period (21.9 per cent). Malformations are almost twice as frequent a cause of death in those at term (26.8 per cent) as in those who succumb in the

premature period (14.2 per cent). Contrary to the commonly stated fact that death in the premature infant is much more likely to be due to intracranial hemorrhage than it is in an infant at term, the opposite is shown to be true by this series of autopsies. Only 12.4 per cent of all the premature infants who were examined at autopsy showed intracranial hemorrhage, while it was present in 22.6 per cent of the term infants who were examined at autopsy. Of 100 premature infants and fetuses and 100 at term, intracranial hemorrhage is found at autopsy only half as frequently in the premature as in the ones at term. However, since neonatal deaths and stillbirths are approximately eighteen times as common in premature infants as in those at term, it may be said that any premature infant alive at the onset of labor and about to be delivered has twenty-one times as many chances of dying from anoxemia, ten times as many chances of dying of a malformation and eleven times as many chances of dying from intracranial hemorrhage as does an infant at term.

No pathologic lesions were demonstrable in 46.4 per cent of the premature fetuses and infants and in 26.4 per cent of the fetuses and infants at term.

Death in an infant or fetus at term is more commonly due to malformation than any other demonstrable cause; death in the premature period is more commonly due to anoxemia than to any other demonstrable cause.

SUMMARY

Although only 6.3 per cent of all infants and fetuses delivered at the Chicago Lying-in Hospital from May 1931 to Jan. 1, 1938, had not reached term before delivery, this group accounted for 59 per cent of the total mortality. In only 57 per cent of all dead infants and fetuses examined at autopsy could a definite pathologic state be demonstrated. This varied from 90 per cent for live born term infants to 44 per cent for premature stillborn infants. In live born infants who died in the neonatal period the most important causes of death were malformations (24.5 per cent), intracranial hemorrhage (23.4 per cent) and anoxemia (12.2 per cent), while in stillborn fetuses the most important causes were anoxemia (23.8 per cent), malformations (12.4 per cent) and intracranial hemorrhage (9.3 per cent). Malformations accounted for a remarkably high proportion of deaths in full term infants who died in the neonatal period (41.7 per cent of those examined at autopsy).

Complications, exclusive of those due to the mechanism of labor, occurred during pregnancy or labor in association with 45.7 per cent of all fetal or neonatal deaths. The most important were toxemia and hemorrhage from premature separation of the placenta or placenta praevia. These were found in association with 33 per cent of the total deaths. Abnormalities of the cord (7.0 per cent), syphilis (1.6 per cent) and other pathologic conditions (3.4 per cent) made up the remaining 12 per cent.

The gross mortality rate does not give an accurate estimate of the role which various types of delivery may play in contributing to fetal and neonatal deaths. A disproportionately large number of premature infants and fetuses delivered by a certain method means a disproportionately high death rate in that group. Eliminating those infants and fetuses that died before the onset of labor, that had not reached the period of viability or in which death was the result of a major malformation gives mortality rates corrected in such a way that some estimate may be made of the effect of various types of delivery. The total mortality (both stillbirths and neonatal deaths) corrected on this basis is 2.5 per cent. If these figures are adjusted so that they represent the total mortality had there been 5 per cent premature infants delivered by each method (the incidence of viable premature infants among all live born infants was 5 per cent) the figures are natural cephalic delivery 1.1 per cent, low forceps 1.3 per cent, mid and high forceps 5 per cent, breech presentation 7.1 per cent, cesarean section 4.1 per cent, version and extraction 13.4 per cent. The total uncorrected mortality is 4.4 per cent.

STUDIES ON THE CIRCULATION IN PREGNANCY

X. SUMMARY OF STUDIES OF THE PHYSIOLOGY OF THE CIRCULATION OF NORMAL PREGNANT WOMEN: A NEW CONCEPT OF THE NATURE OF THE CIRCULATORY BURDEN OF PREGNANCY AND ITS APPLICATION TO THE MANAGEMENT OF CLINICAL PROBLEMS OF PREGNANCY

MOUNT MC GREGOR, N. Y.

Studies were conducted for several years (1932-1937) at the cardiac research laboratory of the Boston Lying-in Hospital on the physiology of the circulation of pregnant women.[1] The purposes of these studies were, first, to learn the dynamics of the circulation of the normal pregnant woman, second, to learn what the nature of the "increased burden" on the pregnant woman with heart disease is, and, finally, to develop, if possible, concepts which might be of clinical use in the management of normal pregnant women and pregnant women with heart disease. A summary of the results of these studies, plus pertinent studies from the literature, will be presented here.

CLINICAL AND LABORATORY EXAMINATIONS

Before proceeding to the physiologic results of this study, it seems useful to present facts bearing on the simpler clinical aspects of the subject gained from the clinical examination of the cardiorespiratory system. This study included single examinations of 3,000 normal pregnant women by us and serial examinations, i. e. monthly examinations of the same patient, of sixty-six more normal pregnant women and of 300 pregnant women with "organic" heart disease. These facts gain importance because knowledge of the normal symptoms of pregnancy may prevent erroneous diagnoses of heart

From the Department of Obstetrics, Harvard University Medical School, and the Cardiac Clinic and Research Laboratory, Boston Lying-in Hospital.

disease in the pregnant woman. They are summarized in the accompanying table. It should be emphasized that normal pregnant women commonly complain of dyspnea. Many of them are orthopneic, that is they breathe more comfortably when they are propped up in bed. Many of them are awakened at night by attacks of palpitations and choking. Complaint of palpitations is common, as is complaint of swelling of the legs and hands. It can be seen thus that symptoms ordinarily attributed to heart disease and heart failure occur normally in the pregnant woman. Obviously such symptoms are also present in pregnant women with heart disease, but by themselves they do not indicate heart disease or congestive failure.

Physical examination during the latter part of pregnancy shows the skin flushed, moderate collapsing pulse and in many instances capillary pulsation over the fingers and the veins dilated over the abdomen and chest. Location of the apex of the heart is difficult because of the large breasts; the pulse is usually rapid and auscultation reveals usually a loud first sound at the mitral area, pulmonic and apical systolic murmurs and the pulmonic second sound commonly louder than the aortic second sound. Pulmonic systolic murmur is demonstrable in late pregnancy by careful physical examination of the heart in 100 per cent of cases and apical systolic murmur in approximately 50 per cent. The signs are those of hyperactive or hyperkinetic heart.[2] Though superficial examination might lead to an erroneous diagnosis of mitral stenosis, more careful examination, with particular note of the absence of diastolic murmur, will lead to the correct conclusion. "Functional" diastolic murmurs are not heard and do not occur because of pregnancy. Swelling of the legs is common. Transient rales almost never occur at the bases of the lungs of the normal pregnant woman. Constant rales at the bases, which never occur in normal pregnant women, are pathologic, and in a pregnant woman with heart disease constitute the most valuable sign of failure. Further discussion of the diagnosis of heart failure in pregnancy is presented elsewhere.[3]

Laboratory studies also show changes during normal pregnancy. Seven foot roentgenograms of the heart sometimes suggest slight enlargement, i. e. the transverse diameter of the heart shadow may exceed by 1 or 2 cm. half the transverse diameter of the chest. There is no crucial evidence to determine whether this is due to displacement or enlargement (hypertrophy or dilatation) of the heart or both. The lungs in roentgenograms show increased markings that could be mistaken for mild congestive failure by one not familiar with x-ray studies of pregnant women. These pulmonary x-ray changes are probably related to an increase in the vascular bed of the lungs and to perivascular infiltration.[4] The electrocardiogram is not remarkable except that a tendency toward left axis deviation as pregnancy progresses has been shown, with a shift back toward normal in the final weeks.[5] The Q wave in lead 3 is deep in 5 per cent of cases,[6] and in the chest lead,[7] with the exploring electrode placed in the fourth interspace 5 cm. to the left of the midsternal line, the T wave may become upright [8] (old technic) for 8 per cent of normal pregnant women and become inverted (old technic) again after delivery. Changes therefore which are sometimes interpreted as being related to coronary artery disease can be seen to occur during normal pregnancy. The white blood cell count [9] in pregnancy may be elevated, that is to from 12,000 to 15,000, and the sedimentation rate of the red blood cells is much increased.[10] It can be seen that use of the white cell count and sedimentation rate as indicators of rheumatic activity in pregnancy without proper corrections might lead to error. Clearcut active rheumatic fever in pregnancy, as a matter of fact, was not seen in this study (300 cases of rheumatic heart disease) and is extremely rare. It should be pointed out that "heart disease" in pregnancy means rheumatic heart disease, for practical purposes, as 91.9 per cent of 850 cardiac patients in this clinic had rheumatic heart disease.

Common Clinical and Laboratory Observations in Normal Pregnancy

I. *Symptoms*
1. Dyspnea
2. Orthopnea
3. "Pseudoparoxysmal nocturnal dyspnea"
4. Palpitations
5. Swelling of legs

II. *Signs*
1. Percussion for cardiac size unreliable
2. Apex beat obscure
3. Loud mitral first sound
4. Apical systolic murmur
5. Loud third heart sound
6. Pulmonic second sound greater than aortic second sound
7. Pulmonic systolic murmur (100 per cent)
8. Tachycardia
9. Extrasystoles
10. Prominent veins
11. Quick pulse (like Corrigan's pulse) and capillary pulse
12. Edema of lower extremities

III. *Laboratory Data*
1. Roentgenogram
   A. Slight enlargement of cardiac shadow
   B. Picture suggests pulmonary congestion
2. Electrocardiogram
   A. Deep Q-3 (5 per cent)
   B. Upright T-4 (old terminology; 8 per cent)
   C. Extrasystoles
3. Sedimentation rate increased
4. White blood cell count increased
5. Red blood cell count, Hemoglobin concentration, Hematocrit reading } decreased

In summary, then, it may be said that in the clinical examination of the pregnant woman, including the clinical laboratory tests, there are signs and symptoms which, unless properly interpreted, might lead to erroneous diagnoses of heart disease, heart failure or rheumatic activity (as shown in the table).

PHYSIOLOGIC STUDIES

The basal pulse rate is accelerated early in pregnancy and averaged, in a group of fifty-one normal pregnant women, 81 beats a minute throughout pregnancy, with

some persons showing a tendency toward gradual increase until term. Post partum the average basal pulse rate dropped to 70 beats a minute.[11] The exact time of return of the pulse rate to normal is unknown as yet.

The basal arterial blood pressure remains within normal limits (the systolic pressure less than 140 mm. of mercury and the diastolic less than 90 mm.) during the course of uncomplicated pregnancy. There seems to be a definite tendency for both average systolic and average diastolic pressure to decrease from the fourth to the ninth lunar[12] month and to increase during the tenth. The diastolic pressure shows a greater decrease, so that there is an increase in pulse pressure. This has been found by other observers[13] and may be associated with the collapsing pulse and the capillary pulse previously described.

The venous pressure in the arms was measured for twenty normal pregnant women (ninety-four observations) and for twenty-seven pregnant women with compensated cardiac disease (144 observations) by the direct method of Moritz and von Tabora[14] and was found to be within normal limits. There was a tendency to diminution during pregnancy and to slight increase post partum, but this was not marked.[15] Elevation of venous pressure measured in the femoral vein in pregnancy has been reported.[16]

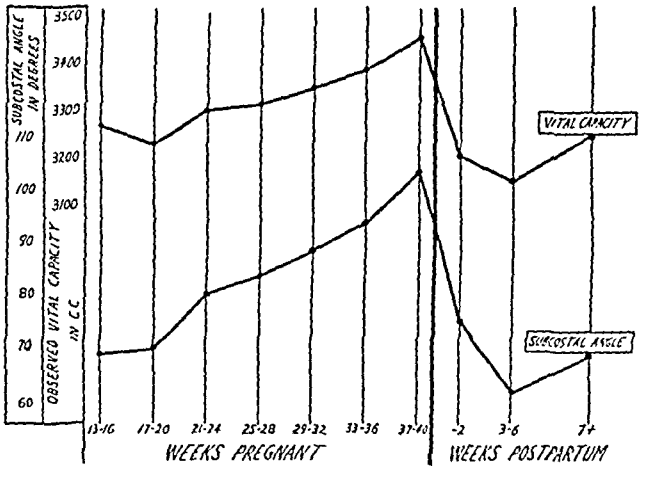

Chart 1.—The relation between the average observed vital capacity and the average curve of values for the subcostal angle in pregnancy. The heavy perpendicular line represents delivery and separates the antepartum and the postpartum period. Note the close correspondence between the two curves, indicating that changes in vital capacity correlate with changes in size and shape of the chest.

Studies of the respiratory system show a marked increase in total ventilation,[17] accompanied with slight but not proportionate increase in oxygen consumption.[18] The average vital capacity, studied in thirty-one normal pregnant women, showed a gradual rise[19] during pregnancy, with a drop post partum. It is of interest that this correlates precisely with the increase in the subcostal angle (chart 1), indicating that the explanation of this slight increase in vital capacity is increase in the size of the chest. Change in size of the chest has been shown further by x-ray studies on measurements of the thoracic cage in this clinic[19] and by studies in the literature.[20] It is commonly believed that the dyspnea of pregnancy is due to the decrease in vital capacity; however, since the vital capacity does not decrease but actually increases, the cause of the dyspnea must be sought elsewhere. The increase in total ventilation without a proportionate increase in the vital capacity is thought to be an adequate explanation for this phenomenon, as it is known that an increase in total ventilation, a decrease in vital capacity or an increase of their normal ratio may cause dyspnea.[2]

It is of note that patients with heart disease showed the same general trend in vital capacity as normal patients, that is, a slight rise during pregnancy and a fall post partum, although the average values were slightly below those of the normal pregnant woman. No patients without heart failure showed a decrease in vital capacity of 8 per cent or more. Hence, a significant drop (15 per cent) in vital capacity in a pregnant woman with cardiac disease indicated impending heart failure and was a practical early sign of failure, preceding the appearance of rales at the bases of the lungs. This point may be illustrated here by one typical case (chart 2). In these patients, as well as in those with cardiac disease whose vital capacity was studied for the first time during heart failure, a return of compensation was accompanied with a significant rise in vital capacity.[3]

Studies were made on the velocity of blood flow by the cyanide method of Robb and Weiss,[21] which utilizes the pathway between a vein and the carotid sinus. One hundred and forty-three observations of the arm-to-carotid circulation time[11] were made on thirty-six normal pregnant women, and the results fell almost without exception in the range for normal nonpregnant women. However, the average velocity of blood flow was normal early in pregnancy, increased at about the seventeenth week of gestation and decreased at the thirty-sixth week, just prior to term. The velocity of blood flow increased immediately post partum and returned to the normal level by the seventh week post partum. This general trend was present in both the peripheral and the pulmonary circulation (112 observations), being more marked in the peripheral circulation and slight in the pulmonary.

Further evidence for speeding of the circulation during pregnancy has been given by simultaneous studies of cardiac output and oxygen consumption.[22] The cardiac output rose out of all proportion to the oxygen

consumption, which of course implies speeding of the circulation, as does demonstration of a decreased arteriovenous oxygen difference during pregnancy. The slowing of the circulation in the latter part of pregnancy, as demonstrated in our studies, is further corroborated by the waning of the disproportion between cardiac output and oxygen consumption during the last months of pregnancy and as the cardiac output decreases.

The cardiac output during pregnancy, according to other studies,[23] shows a gradual increase during early pregnancy, with the maximum cardiac output appearing from the sixth through the ninth lunar month. A definite decrease in cardiac output, which may even bring the value back to its normal level, occurs during the tenth lunar month. In most cases, however, the normal level is attained within several weeks after delivery.

Not only does the cardiac output during rest show an increase during pregnancy, but in addition the increase in cardiac output with exercise is disproportionately greater in pregnant women than in normal nonpregnant ones.[24]

It will be seen then that the circulation of the blood speeds up from week to week of pregnancy and slows up as the puerperium approaches. It can be seen further that corresponding with this the heart pumps more blood a minute during the same period when the blood is flowing faster. Also at the time that the circulation slows, that is, during the last four to six weeks of pregnancy, the heart pumps less blood a minute.

Studies were made of the total amount of blood in the body and its composition. Studies of total blood volume during pregnancy have been at variance but usually reported an increase.[25] One hundred observations on blood volume in pregnancy, made at this clinic [26] by the colorimetric method of Keith, Rowntree and Geraghty,[27] showed a higher value than that of the nonpregnant state, which merely corroborated the data of most previous observers. However, it was felt that the technical errors incident to this method made it valueless for the study of the exact changes from month to month for pregnant women and that such a study must await the development of a more precise method for blood volume determination. The spectrophotometric method of Gibson and Evans [28] provided the needed precision, and by this method it was possible to discover for the first time, with fourteen women on whom fifty-six determinations (forty ante and sixteen post partum) were made at intervals during pregnancy, the exact trend of the change in blood volume. It was found that there was a progressive increase in plasma volume from early pregnancy through the ninth lunar month, when a maximum was reached, and then a decrease in the tenth lunar month. This decrease continued post partum, so that by the end of the second week the volume had reached the normal level for nonpregnant women. At the period of maximum increase the average increase is 65 per cent above the average value for normal nonpregnant women. The total cell volume, measured by the the hematocrit, also changed during pregnancy, following the trend of the plasma volume. The total blood volume increased to a maximum of 45 per cent over the value for normal nonpregnant women at the height of increase. The cause of increase in plasma volume is not known, but since the outstanding conditions in which blood volume is profoundly disturbed, such as exophthalmic goiter, myxedema and Addison's disease,[29] are due to endocrine disturbances, it is thought that the endocrine disturbance in pregnancy offers the most reasonable point for study. Moreover, there is a striking but not exact resemblance of the trend of plasma volume to that of excretion of gonadotropic substance in normal pregnancy.[30] The demonstration of the sodium and water

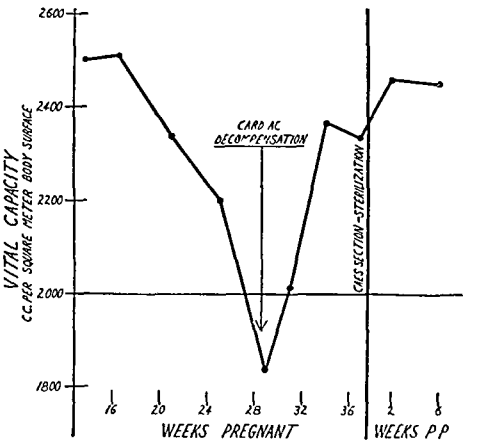

Chart 2.—The vital capacity before, during and after heart failure in a pregnant woman suffering from severe rheumatic heart disease. Note the steady decrease in vital capacity which preceded the appearance of clinical cardiac decompensation, i. e., weakness, cough and rales at the bases of the lungs. Compensation was restored with bed rest, restriction of fluids and administration of digitalis; this was accompanied with a rise in the vital capacity. The decrease in vital capacity is a warning of impending clinical heart failure.

retaining effect of the estrogenic and androgenic substances [31] lends further support to the speculation that the increase in blood volume in pregnancy may be endocrine determined. The increased blood volume may well cause the increased cardiac output. It has been shown experimentally that increased blood volume leads to increased cardiac output; [32] how far the results of studies in which blood volume is raised acutely apply to pregnancy, in which blood volume is increased over a long period, is not known.

Studies of the red blood cell count and hemoglobin and hematocrit readings showed changes which correlated inversely with the change in plasma volume, that is, as the plasma volume increased, the red blood cell count, hematocrit reading and hemoglobin per unit volume of blood decreased. These studies showed return toward normal before delivery and not post

partum and supplemented the original observations of Kühnel.[33] The mean corpuscular volume of the red cells was relatively high during pregnancy, reaching an average maximum of 90.9 cubic microns (twelve cases). It can be seen therefore that the increase in plasma volume accounts in part at least, as has been stated before,[34] for the so-called physiologic anemia of pregnancy.

No severe anemia developed in the patients studied throughout pregnancy, and one might add the general clinical statement that in the absence of infection, such as pyelitis, or of inadequate diet, no severe anemia was noted at this hospital in patients known to have normal blood before the onset of pregnancy. In other words,

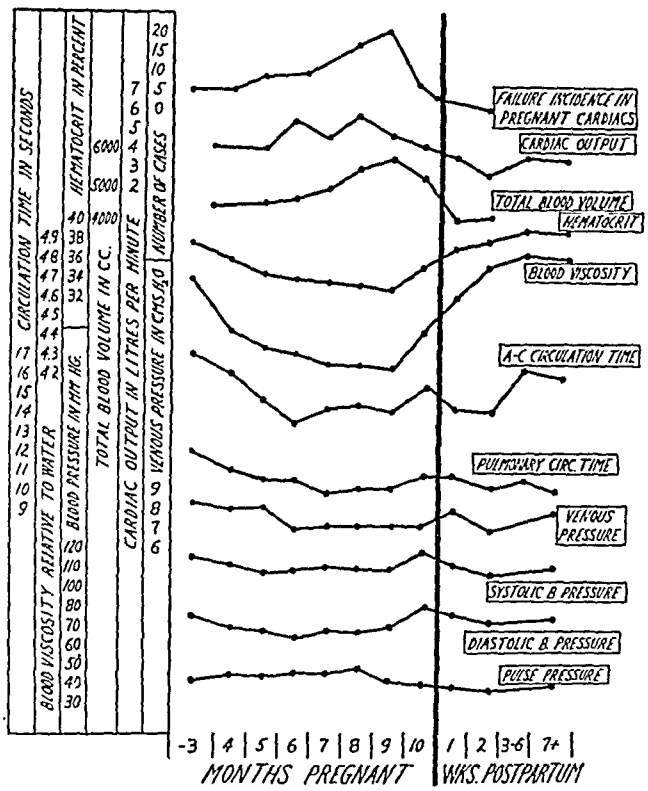

Chart 3.—A summary of the studies of the circulation in pregnancy. The heavy perpendicular line represents delivery and separates the antepartum and the postpartum period. The data on cardiac output are taken from Burwell[37a] and the others from our work. The total blood volume and cardiac output have similar trends, i. e., increase during the early part of pregnancy and decrease in the last months. The viscosity of the blood and the hematocrit reading, which correlate fairly well with the hemoglobin concentration of the blood, show decrease during early pregnancy and increase during the last months. The curve for circulation time parallels somewhat that of the blood viscosity, that is the blood flows faster when thinner. It also suggests that the blood flow is most rapid at the time of the greatest blood volume and cardiac output, with coincident return toward normal with these two functions. The venous pressure remains within normal limits and is constant for the last five months of pregnancy, with a slight postpartum rise. Both the systolic and the diastolic arterial blood pressure showed a slight rise in the last month of pregnancy, although the patients were normal and not "toxemic." It should be emphasized that after the eighth month, when there is maximum incidence of heart failure, there is return toward normal of values for blood volume, blood flow (circulation time, cardiac output) and blood content (hematocrit reading, viscosity). The incidence of heart failure decreases, corresponding with this return to normal of the circulatory functions.

our experience has been that normal pregnancy may accentuate anemia but not alone cause severe anemia.

Calculations of the viscosity of the blood during pregnancy, from studies of thirty-six women, show that it decreases, reaching a minimum during the ninth lunar month, commences to return toward normal, that is, becomes more viscid, in the tenth lunar month and reaches normal in the puerperium.[11]

It will be noted (chart 3) that the viscosity varies with the circulation time, that is, the thinner the blood, the faster it flows during pregnancy. This follows a well known physical law (Poiseuille's) which states that the less viscous the liquid, the more rapid its flow, all other factors being equal. Actually this may operate through increased cardiac output.

No adequate studies have been made of the veins, arteries and capillaries during pregnancy. Infra-red photographic studies[35] of the superficial veins of the normal pregnant woman have been made at this clinic. These showed clearly marked venous dilatation over the breasts and abdomen, with disappearance of the dilatation over the abdomen after delivery but persistence of the changes over the breasts until lactation ceased.

The placental circulation is of interest, as it is composed[36] of arteries connecting with veins through large vascular spaces without the interposition of other capillaries. This arrangement in the maternal portion of the placenta presents certain similarities to an arteriovenous fistula. This arrangement of the placental circulation has been suggested by Burwell[37] in an interesting presentation as an important factor in causing changes in the circulation during pregnancy. However, it does not appear to explain completely all the observed changes and as yet has not been demonstrated to be consistent with the fact of return toward normal before delivery of some of the circulatory functions.

A summary of the actual physiologic changes, as pictured in chart 3, gives a fairly clear idea as to some aspects of the increased burden on the heart in pregnancy. As pregnancy progresses the blood volume, the cardiac output and the velocity of blood flow increase. These increases commence early in pregnancy and progress steadily during pregnancy, reaching a maximum during the ninth lunar month. In the last month a return toward normal begins, with a consequent lightening of the burden on the heart.[37a] In other words, contrary to popular belief, the return toward normal does not begin at delivery but at a period preceding it. Further evidence supporting this concept comes from electrocardiographic studies[5] from this clinic, in which, as mentioned before, it was demonstrated that the left axis deviation of pregnancy begins to diminish not post partum but in the final weeks of pregnancy; x-ray studies of heart volume[38] also revealed a tendency to decrease toward normal not post partum but in the final weeks. If this concept of the circulatory burden is correct, how does it correlate with clinical experience?

If one examines the curve of onset of heart failure in pregnant women[39] with heart disease at this clinic,[40]

one observes that the highest incidence of heart failure is at the time when physiologically the burden on the heart is greatest. As the physiologic burden decreases, the incidence of failure decreases.[37a] Further evidence supporting this concept is drawn from the clinical improvement during the final month of pregnancy in the circulatory status of patients with chronic congestive heart failure. Obvious and clearcut clinical improvement has occurred in such patients, who, although at strict bed rest and under optimum treatment for several weeks or longer, had previously failed to show significant change. In other words, as the circulatory burden diminished during the tenth lunar month of pregnancy, there was associated clinical improvement of congestive failure in patients of the type described (chart 4). The practical lesson to be drawn from this is that in early pregnancy, with the burden increasing, the onset of heart failure usually demands termination of the pregnancy after compensation is restored. In the latter part of pregnancy one may safely await, in most instances, delivery through the pelvis at term, as the circulatory burden can be expected to decrease before delivery. One might almost be tempted to add a statement to the effect that one should be especially careful with pregnant cardiac patients during the sixth to ninth lunar months and supervise them most closely during that period, as it is the period of increasing burden; however, these patients must be supervised carefully during the entire course of pregnancy. Of course these rules are not absolute; they are, however, of great practical value and are based on both physiologic and clinical observations. The results in this clinic of treatment based on these rules [41] bear further testimony to their validity.

There are no quantitative studies which throw any light on the question as to which constitutes the greater "strain" on the heart, pelvic delivery or cesarean section. In the absence of quantitative studies we may venture the clinical impression that labor as conducted in cases of cardiac disease [42] at the Boston Lying-in Hospital is not a particularly great burden on the heart, probably not a greater one than the activities of the patient at home preceding labor or those attendant on the care of the child after delivery. As compared with cesarean section, with its common postoperative accompaniments of pain, distention and slight fever, delivery through the pelvis, as described, would seem to be associated with much less "cardiac strain." However, the proper evaluation of these two methods of delivery is an obstetric problem and probably will always remain one.

As a result of our studies covering five years, a few general points suggest themselves which may be helpful to others who plan to study the problems of pregnancy. Before studying pathologic problems in pregnancy it is wise to become acquainted with normal pregnancy, both the physiologic and the clinical picture. The normal pregnant woman varies in many ways from the nonpregnant woman, and many errors have been made because of the lack of appreciation of this fact. Though one cannot attribute to the pregnancy all changes that occur in a pregnant woman, certain specific and characteristic changes do occur in normal pregnancy and should be recognized. The most fruitful studies of pregnancy seem to be those begun in the early part and continued through delivery and into the postpartum period. In a series of pregnant women, a significant number have some complication, such as toxemia, pyelitis or hemorrhage, which vitiates the study; therefore it is advisable to allow for this by starting with a larger number of patients than would otherwise be necessary. The obstetric literature is sadly lacking in studies on patients observed before the first pregnancy and through several pregnancies and the intervening periods. Complete studies of this type would no doubt settle many disputed points and seem indicated.

SUMMARY AND CONCLUSIONS

A careful evaluation of the variations in the cardiovascular status of the normal pregnant woman, with special regard to signs and symptoms, is necessary for avoidance of erroneous diagnoses of heart disease in normal pregnant women or heart failure in pregnant women with heart disease.

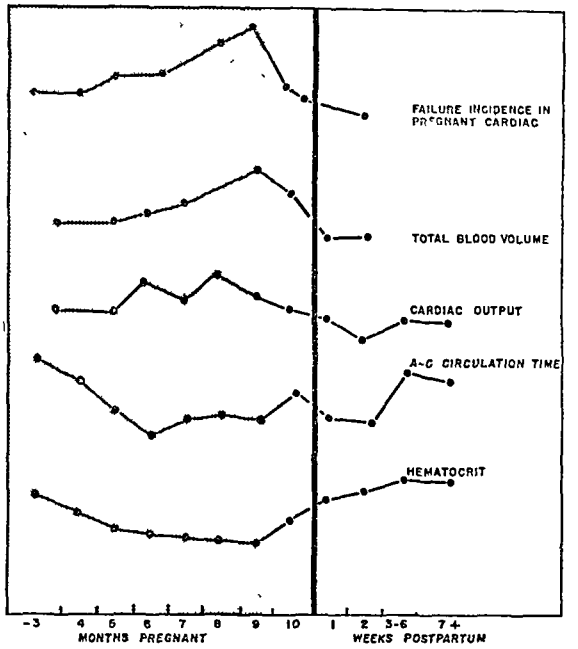

Chart 4.—Circulatory burden on the heart in pregnancy. The dark area shows the time of increasing physiologic burden on the heart coincident with the increase in incidence of heart failure; the unshaded area shows the decrease of the burden ante partum, with coincident decrease in the incidence of heart failure. The heavy perpendicular line represents delivery and separates the antepartum and the postpartum period. Quantitative data for these curves appear in chart 3. The curve for cardiac output is from the data of Burwell.[22]

The vital capacity usually increases slightly during pregnancy; a significant decrease in vital capacity in a pregnant woman with heart disease forecasts impending heart failure and provides the earliest objective sign of it (charts 1 and 2).

The results of the physiologic studies of the circulation of pregnant women which contribute most information as to the circulatory burden may be summarized as follows:

1. The blood volume, velocity of blood flow and cardiac output increase during pregnancy to the ninth lunar month and then decrease prior to delivery.

2. The hemoglobin content and red corpuscle count per unit volume of blood and the hematocrit reading and viscosity of the blood decrease during pregnancy to the ninth lunar month and increase prior to delivery (chart 3).

Active rheumatic fever is not a significant factor contributing to heart failure during pregnancy and is notably rare at that time.

The significant factors predisposing to heart failure in pregnancy are, however, the physiologic changes just described, particularly the increase in blood volume, cardiac output and velocity of blood flow.

The onset of heart failure in pregnant women with cardiac disease occurs most frequently at the phase of pregnancy associated with the maximum increase in blood volume, velocity of blood flow and cardiac output. The frequency of heart failure diminishes during the last weeks of pregnancy and corresponds to the decrease in the values of these circulatory functions (chart 4).

It follows from both physiologic and clinical observation that heart failure in early pregnancy may be expected to grow worse as the circulatory burden increases and to improve during the predelivery period, as the circulatory burden diminishes.

THE MECHANISM OF ACTION OF QUININE IN MYOTONIA AND MYASTHENIA

A. M. HARVEY, M.D.

LONDON, ENGLAND

Wolf [1] was the first to point out the ability of quinine to relieve the difficulty in the muscular relaxation of patients with myotonia congenita and myotonic dystrophy. Later Kennedy and Wolf [2] commented on the increase in muscular weakness produced in patients with myasthenia gravis by the administration of quinine and, conversely, the increase in the degree of myotonia after the administration of prostigmine. These observations were fully corroborated by Kolb and his associates,[3] who suggested that prostigmine would be of value when diagnosis was difficult, as in the condition described by Curschmann [4] of myotonia sine myotonia. These authors also observed that small amounts of prostigmine could completely counteract the beneficial effect of quinine in myotonia, even when large doses of the latter drug were used. Harvey and Whitehill [5] had previously discussed the value of quinine in the diagnosis of early cases of myasthenia gravis, when the objective improvement following prostigmine was not sufficiently clear cut. They also pointed out that alarming symptoms of respiratory distress and dysphagia might result when a small dose of quinine was given to a patient with moderately severe symptoms of myasthenia.

In its actions on these two diseases potassium chloride has been found to exhibit a similar contrast, but in the opposite direction. Laurent and Walther [6] recorded improvements in myasthenia after oral administration of large amounts of potassium chloride, which they tried because of the observation of Feldberg and Vartiainen [7] that it increased the sensitivity of the response of the superior cervical ganglion of the cat to acetylcholine and to stimulation of the preganglionic nerve. Russell and Stedman [8] pointed out that it had an action similar to that of prostigmine in increasing the severity of the symptoms in myotonia.

Kennedy and Wolf [2] suggested that quinine was able to relieve myotonia by inhibiting the action of acetylcholine liberated at the motor nerve endings. As evidence in favor of this view they quoted the work of Stavraky,[9] who found that quinine acts directly as a paralyzing drug on the secretory fibers of the fibers of the auriculotemporal nerve. It was found, however, to inhibit the secretory effect of acetylcholine itself on the submaxillary gland, though physostigmine tended to restore to normal the action of the chorda tympani paralyzed by quinine. However, no really satisfactory explanation of these actions of quinine on diseases of human muscle has yet been formulated.

A pharmacologic investigation of the effects of quinine on neuromuscular conduction and on the contractile properties of skeletal muscle [10] has revealed certain features of its effects, which suggest an explanation of its mode of action in these diseases, though the complete explanation must await more adequate knowledge of the pathogenesis of myotonia and myasthenia. Only those of its effects which are concerned with the action of quinine in these two diseases will be discussed here. These are as follows:

1. Quinine decreases the ability of the muscle to respond to and to hold a tetanus. This is due to an effect directly on the muscle, which increases its refractory period.

2. The excitability of the motor end plate is lowered, so that the response to nerve stimulation is reduced. This is best seen in a partially curarized muscle. When quinine is injected under these conditions, the curarization becomes complete. This action is also in large part responsible for the abolition by quinine of the quick response of a muscle to injected acetylcholine. For other features of the action complicating this picture, reference may be made to my full paper on the pharmacologic effects. Brown and his associates [11] had previously shown that curarine could remove the response to injected acetylcholine more readily than response to a motor nerve volley.

3. The normal potentiation of the twitches caused by physostigmine, and due to repetitive response to a single nerve volley, is prevented by the previous administration of quinine or is counteracted promptly when the drug is injected during a period of potentiation. Weiss [12] had found that the fibrillary twitchings produced in the cat by physostigmine were abolished by the intravenous injection of quinine.

4. The repetitive response to a single stimulus which occurs after veratrine is also removed by quinine. This occurs in both the normal muscle and the muscle of which the motor nerve has previously been cut and allowed to degenerate.

These observations offer a fairly satisfactory explanation of the effects of quinine in myotonia and myasthenia gravis, and also of the opposing action of prostigmine in these two conditions.

Although the exact nature of the disturbance in myasthenia gravis is not known, it has long been likened to partial curare poisoning [13] and, as such, attributed to a diminution in the excitability of the motor end plates in the involved muscles. Blake Pritchard [14] has shown that these muscles are not capable of maintaining a tetanus with a high frequency of nerve stimulation, although the tension developed in response to less rapid stimulation is normal and well maintained. His experiments again afford evidence for a depression of motor end plate response, a similar type of response occurring in a partially curarized mammalian muscle.[15] Lindsley [16] recorded the action potentials of voluntary contractions of single motor units in patients with this disease and found that they show an abnormal fluctuation in amplitude. This suggests that all the fibers in the single motor unit do not respond to every nerve impulse. These observations could be interpreted by supposing that the end plate threshold is raised in these patients or, as an alternative, that the concentration of acetylcholine released by an impulse is subliminal for the stimulation of some of the fibers. Any drug which has a curariform action, as quinine has, would in either case cause an increase in the severity of the symptoms. Physostigmine or prostigmine might act by retarding the destruction of normally subliminal charges of acetylcholine liberated at some motor nerve endings. On the other hand, the possibility is not excluded that these alkaloids may have an effect in lowering the threshold of end plate excitability, independent of their antiesterase actions. The fact that guanidine will relieve the myasthenic condition, as recently demonstrated by Minot and her associates,[17] shows that antiesterase action is not necessarily involved in such a remedial effect. Guanidine has no appreciable antiesterase action.[18] It may be noted in that connection that quinine, which has an opposite action to that of prostigmine in myasthenia, also has a definite, though relatively weak, inhibiting effect on the action of cholinesterase.[19]

The localization of the disturbance in myotonia is much less certain. Lindsley and Curnen [20] have demonstrated oscillatory action potentials during the period of the slow relaxation. They express the opinion that this indicates a neurogenic rather than a myogenic phenomenon, and they advance the hypothesis that the after-contraction is of reflex origin and due to persistent discharge of hyperexcitable end organs in the muscle. This theory, however, does not seem tenable, since anesthesia of the motor nerve does not abolish myotonia mechanically produced, as shown by Schaefer,[21] nor does spinal anesthesia, as demonstrated by Kennedy and Wolf.[2] In view of the fact that myotonia presents a contrast to myasthenia, both in its clinical features and in the responses given to various drugs, it seems most likely that the abnormality is one of neuromuscular transmission, the threshold of the end plates being lower, or the transmitter of excitation from the nerve endings being more slowly destroyed, than in the normal muscle. The response of the myotonic muscle to a single nerve volley would then, in either case, be similar to that of a muscle under the influence of physostigmine in that it would respond repetitively. Any drug with a curare-like action on the excitability of the end plates would then diminish this effect and alleviate the myotonus. On the other hand, it has been shown by Wilson and Wright [22] that potassium ions have an antagonistic effect to that of curare and lower the threshold at the motor end plates. It is therefore in accordance with expectation that potassium salts are beneficial in myasthenia gravis and increase the severity of myotonus.

There still remains, however, the possibility that myotonia is due to an abnormality of the whole muscle fiber rather than of the end plate alone, resembling that of a muscle treated with veratrine. It has been shown that the refractory period of skeletal muscle is increased by quinine and that this causes a diminution in the ability of even a denervated muscle to hold a tetanus and likewise abolishes the repetitive nature of the response under veratrine. This action of quinine would explain its effect in relieving myotonus, if this abnormality was due to a change in the muscle fibers, causing them to respond repetitively to a stimulus of any kind and not merely to the normal excitation through the nerve.

On the whole, however, my results with quinine strengthen my belief that the disturbances in these two diseases are at the motor end plates. Such a conception gives a reasonably satisfactory explanation of the effects of various drugs on the two conditions; but there is, as yet, no clue to the fundamental processes responsible for the suggested alterations in end plate excitability.

SUMMARY

1. The existing evidence suggests that myasthenia gravis and myotonia are due to abnormalities of neuromuscular transmission. If these are regarded as due to changes in the excitability of the motor end plates of the muscles involved, the excitability would be lower in myasthenia and higher in myotonia than in the normal muscle.

2. Quinine has a curare-like action by which it decreases the excitability of the end plates. This effect would account for its ability to improve myotonia and to increase the severity of the myasthenic state. Physostigmine and potassium chloride, as would be expected, both produce effects on these two conditions, which are in each case the opposite of those produced by quinine.

SPONTANEOUS PNEUMOTHORAX IN ANTHRACOSILICOSIS

MARTIN J. SOKOLOFF, M.D.
AND
JOHN T. FARRELL JR., M.D.
PHILADELPHIA

Interest in the pulmonary dust diseases has been stimulated by their inclusion in many states among the compensable occupational diseases. The pathologic clinical and roentgenologic aspects of the pneumoconioses have been extensively described.

Spontaneous pneumothorax complicating pneumoconiosis has been reported from time to time, but there appear to be no definite data as to its frequency. Furthermore, there are no studies comparing the incidence of the condition in simple pneumoconiosis with the incidence in pneumoconiosis associated with tuberculosis.

Most reports concern pneumocotic tuberculosis, and Ickert [1] has stated that according to his experience and that of Redeker pneumothorax is found in pneumoconiosis only when the pneumoconiosis is associated with tuberculosis. During the past few years, however, spontaneous pneumothorax occurring in cases of pneumoconiosis without complicating tuberculosis has been reported with increasing frequency. Hofbauer [2] in describing such a case discussed two similar ones which had come to his attention. Ketterer,[3] Snyder,[4] Breton and Eloire [5] and Brulé and his co-workers [6] have considered this condition of sufficient rarity to report individual cases in detail. De Léobardy and Pasquet [7] have called attention to a case of bilateral pneumothorax occurring under similar conditions.

TABLE 1.—*Summary of Cases*

	Number of Cases	Cases of Pneumothorax	Percentage
[illegible]	199	7	3.5
[illegible]	308	14	4.5
By carcinoma	1	1	
Total	507	22	

To determine the frequency of spontaneous pneumothorax as a complication of pneumoconiosis, we have reviewed the records of 507 anthracite coal miners incapacitated by chronic pulmonary disease. All these men had anthracosilicosis; 308 (60.7 per cent) had coexisting pulmonary tuberculosis and one had metastatic pulmonary carcinomatosis.

Pneumothorax occurred spontaneously in twenty-two (4.3 per cent) patients. Among the 199 patients with simple anthracosilicosis it was found in seven (3.5 per cent). Among the 307 patients with coexisting tuberculosis it was seen in fourteen (4.5 per cent); it also occurred in one instance in association with pulmonary metastasis (0.3 per cent) (table 1).

The ages of the patients ranged from 25 to 52 years and they had been exposed to mine dust for periods ranging from three to thirty-six years (table 2).

Eight patients had second stage and fourteen third stage anthracosilicosis. In three instances the pneumothorax was bilateral, in nineteen unilateral. Of the cases of unilateral involvement, the left side was affected in eleven and the right side in eight.

In five patients pleural effusion developed. In three the anthracosilicosis was uncomplicated; in two there was coexisting tuberculosis. In only one, however, was there sufficient fluid to require removal.

Of the seven patients with uncomplicated anthracosilicosis, one died. Of the fifteen with a complication, the patient with carcinomatosis and ten of the fourteen with tuberculosis died.

The diagnosis of uncomplicated anthracosilicosis was made by applying the criteria for the differentiation of simple anthracosilicosis from anthracosilicotic tuberculosis described by one of us (M. J. S.).[8] Repeated analyses of the sputum showed no tubercle bacilli, and no evidence of tuberculosis was found on serial x-ray examination. In addition, there was no severe hemoptysis, marked toxemia or extensive cavity formation and no extrapulmonary tuberculous complication. In one case no evidence of tuberculosis was seen at necropsy.

CLINICAL AND ROENTGENOLOGIC FEATURES

Advanced pneumoconiosis is always associated with inflammatory reaction in the pleura, and in this group of anthracosilicotic patients evidence of extensive adhesions was found in every case. The symptoms produced by rupture of the pleura appeared to depend primarily on the extent to which the pleural space was obliterated by these adhesions and were in the main the result of further reduction of the breathing capacity in persons already having considerable dyspnea because of preexisting pulmonary disease.

In a few patients small encapsulated collections of air were seen. These produced no symptoms and were discovered only by routine x-ray examination; the air was eventually absorbed and the clinical course unaffected. In all but one case the localized pneumothorax was located in the upper part of the chest.

In patients in whom the pleural surfaces were sufficiently free to permit the collection of a large amount of air, perforation of the pleura was of serious consequence. Perhaps the most striking feature in this group was the extreme distress caused by a combination of intense dyspnea and a sense of impending suffocation. Severe pain in the chest and a feeling of constriction or pressure on the affected side were common complaints, and the symptoms of shock were present in many cases.

The severe reactions precipitated by spontaneous perforations of the pleura were poorly borne. This was especially true of the patients who prior to the accident were greatly debilitated or markedly dyspneic. The severity of this accident is reflected in the high mortality with which it is associated, particularly in the group with superimposed tuberculosis. One patient died within a few minutes after the accident, one three hours after and two within twenty-four hours.

The x-ray picture of pneumothorax in association with anthracosilicosis has certain distinctive characteristics. The dust-laden lung, containing as it does an excessive amount of fibrous tissue, is still of considerable volume, even when collapsed under high pressure. There are in addition, nearly always, extensive adhesions which partially anchor the lung to the wall of the chest at one or more points. Because of these two factors, the increased density of the lung parenchyma and the adhesions, the compressed lung is not as greatly reduced in volume as when pneumothorax occurs in other conditions, nor is it pushed as far downward and backward; instead, it is suspended as a compact mass in the pneumothorax cavity. The fixed semirigid lung acts as a shield and prevents the full force of the increased pressure from being directed against the heart and the mediastinal structures. Thus shifting of the heart and mediastinum is not as extreme as with high-tensioned pneumothorax associated with other conditions. The main force is exerted on the diaphragm and the thoracic wall, so that downward displacement of the diaphragm and increase in size of the thorax on the affected side are nearly always present, particularly if the pneumothorax space is large.

Roentgenologically, pneumothorax has to be differentiated from emphysematous blebs and pulmonary cysts. The three conditions are characterized by increased aeration of a part of the pulmonary fields. However, attenuated bands of pulmonary tissue can usually be made out in the blebs and cysts, while they are absent in pneumothorax. When the pneumothorax is large or occupies the lower lateral aspect of the thoracic cavity, the edge of the lung can be seen. The pneumothorax frequently changes in size, while blebs and cysts present a more or less constant appearance.

BILATERAL SPONTANEOUS PNEUMOTHORAX

Simultaneous bilateral spontaneous pneumothorax complicating pneumoconiosis is rare. In a comprehensive review of the literature Glickman and Schlomovitz [9] found only six cases, and to these they added one of their own.

Our series of twenty-two cases includes three in which the perforations were bilateral. One of these has been previously reported by Norris and Landis [10] and is included in the group collected by Glickman and Schlomovitz.

CASE 1.—A man aged 41, who had been employed in the mines for twenty-nine years, had third stage anthracosilicosis complicated by tuberculosis, with tubercle bacilli in the sputum. There was a great amount of air in both pleural cavities, but this was entirely absorbed before his death, which occurred three months after the perforation.

CASE 2.—A man aged 43, who had been exposed to mine dust for ten years, had third stage anthracosilicotic tuberculosis, with tubercle bacilli in the sputum. The pneumothorax was asymptomatic, with a collection of air along the lateral margin of the upper lobe of the right lung and a small pocket of air over the upper lobe of the left lung. This patient also died.

CASE 3.—A man aged 51, who had been engaged in coal mining for thirty-six years, had perforations which occurred suddenly and were characterized by severe pain in the chest and collapse. X-ray examination revealed advanced third stage pneumoconiosis, with both lungs partially compressed by pneumothorax. On the right side the air collected at the base and on the left over the upper lobe. No tubercle bacilli were found in the sputum on repeated analyses, but the patient was considered to be tuberculous because of the x-ray picture and the severe toxemia. He is still under treatment, and with him also there has been absorption of the air, with complete reexpansion of both lungs.

CONCLUSIONS

Conditions which favor the development of spontaneous pneumothorax are always present in anthracosilicosis, either as a direct result of the action of the dust or as a complication. Emphysema, which plays an important part in the production of spontaneous pneumothorax, is a constant accompaniment of anthracosilicosis. Bleb formation is frequent in association with this emphysema, and the tendency of the blebs to rupture constitutes a hazard in every anthracosilicotic patient. The possibility of the development of pneumothorax is further increased by the presence of adhesions, which may be responsible for the entrance of air into the pleural space by tearing the visceral pleura at their insertions. The coexistence of tuberculosis was another factor contributing to pleural accidents. Since tuberculosis is considered the most common cause of spontaneous pneumothorax, it is reasonable to assume that this condition should occur frequently in patients with anthracosilicotic tuberculosis. The severe cough, which is a predominant symptom; supplements the influence of these three factors, and the resulting strain may cause rupture of the pleura at its weakened points.

TABLE 2.—*Distribution of Cases*

Case Number	Age	Years of Mining	Stage	Type	Result
			Uncomplicated Anthracosilicosis		
1	47	20	2	Left hydropneumothorax	Unimproved
2	36	15	3	Right pneumothorax	Died
3	33	12	2	Left pneumothorax	Improved
4	50	27	3	Left hydropneumothorax	Improved
5	45	26	3	Left hydropneumothorax	Improved
6	37	13	2	Right pneumothorax	Improved
7	37	25	3	Right pneumothorax	Improved
			Anthracosilicosis Complicated by Tuberculosis		
1	51	30	3	Right hydropneumothorax	Unimproved
2	48	28	2	Left pneumothorax	Improved
3	51	25	3	Right pneumothorax	Died
4	39	17	2	Left pneumothorax	Died
5	50	27	3	Right hydropneumothorax	Died
6	36	18	3	Left pneumothorax	Died
7	41	29	3	Bilateral pneumothorax	Died
8	48	24	2	Left pneumothorax	Died
9	43	10	3	Bilateral pneumothorax	Died
10	25	3	2	Right pneumothorax	Died
11	36	13	2	Left pneumothorax	Died
12	51	36	3	Bilateral pneumothorax	Improved
13	52	30	3	Left pneumothorax	Died
14	48	28	3	Left pneumothorax	Improved
			Anthracosilicosis Complicated by Carcinomatosis		
1	48	25	3	Right pneumothorax	Died

It would appear therefore that in anthracosilicotic patients there exists a combination of conditions which are ideal for the development of spontaneous pneumothorax. However, in spite of the presence of so many factors which tend to produce perforations of the pleura, the accident occurred in only twenty-two (4.3 per cent) of a group of 507 anthracite coal miners.

The reason for this low incidence is revealed by study of the pathologic changes resulting from irritation by the dust. In most patients there is an inflammatory reaction in the visceral pleura accompanying that in the lung. This progresses as the amount of dust in the lung increases, so that in the extreme grades of anthracosilicosis tremendous pleural thickening results. In other patients both the visceral and the parietal layers of the pleura are involved in the reaction, leading to

obliteration of the pleural space. Since the thickened or adherent pleura can be neither perforated nor torn easily, it affords definite protection against the development of spontaneous pneumothorax and tends to overcome the effect of the factors producing the condition.

SUMMARY

Twenty-two cases of spontaneous pneumothorax were found among 507 coal miners disabled by anthracosilicosis (4.3 per cent). Seven cases were among 198 patients with simple anthracosilicosis (3.5 per cent) and fourteen among 308 patients with coexisting tuberculosis (4.5 per cent). In one case the lesion occurred in association with pulmonary metastasis.

In three instances the pneumothorax was bilateral. Two of these, reported here for the first time, make a total of nine cases of bilateral spontaneous pneumothorax in pneumoconiosis reported in the literature to date.

The conditions may be either asymptomatic or associated with severe symptoms; for the latter type the prognosis is grave.

Emphysema, pleural adhesions, tuberculosis and the accompanying severe cough favor the development of pneumothorax in anthracosilicosis.

The effects of these forces are largely overcome by thickening of the visceral pleura or obliteration of the pleural cavity, practically constant features of anthracosilicosis.

255 South Seventeenth Street.

POSTURAL TREATMENT OF ACUTE LARYNGOTRACHEOBRONCHITIS

T. C. GALLOWAY, M.D.

EVANSTON, ILL.

With tragic abruptness a child with an apparently ordinary infection of the upper respiratory tract with moderate difficulty in breathing may choke up suddenly, fight desperately for air for a short time and die, and at autopsy the appearances of acute laryngotracheobronchitis are found. Though there may have been few physical signs, the tracheal and bronchial mucosa may be red, thick and even ulcerated, the bronchi and bronchioles may be filled with thick secretions, plugs or crusts, and areas of the lungs may be atelectatic or emphysematous.

Some men have never recognized such a condition and consider it a rarity. Others who have not seen what early and proper treatment can do for it think it hardly more than an academic problem to be studied post mortem. In the light of published experiences there can be no doubt that it occurs often and that, while it is serious, with decision, energetic treatment and unremitting care the prognosis may not be bad. Ten cases of this condition in which cannulation was required are here reported, with two deaths.

A rather clear picture of the condition has been given in the past twenty years by Baum,[1] Gittins,[2] Jackson,[3] Richards,[4] Smith[5] and others. Certain facts seem to have been rather definitely established, and these will be briefly reviewed. If not indeed a true clinical entity, it has definite recurring characteristics determined by anatomic, physiologic and bacterial factors. Its occurrence is not very rare, and it may be reported more often when it is generally appreciated and recognized. The mortality, according to Jackson,[3] averages 70 per cent, although large group reports vary from 33 to 75 per cent.

Symptoms are likely to include those of a mild infection of the upper part of the respiratory tract followed by cough, hoarseness, increasing stridor, restlessness, dehydration, sepsis of varying degree and signs of cardiac and general exhaustion. Obstructive symptoms usually dominate the picture, though these may be slight if the obstruction is low in the bronchial tree or if sedatives have been given. Cyanosis is an alarming symptom, especially the pale cyanosis of exhaustion seen perhaps more often in low obstruction. The severity of symptoms is out of proportion to physical and roentgenologic observations.

Primary involvement may be chiefly of the larynx or subglottic areas, of the trachea or of the bronchi. Usually the process appears to descend from the larynx and the whole respiratory tree is likely to suffer. Richards[4] and others have well described the end state seen post mortem, and the Jacksons[3] have given in detail the living pathologic picture as related to the symptoms.

Diagnosis should not be difficult. Diphtheria, foreign body, croup, laryngismus stridulus and other causes of respiratory difficulty are to be ruled out, if necessary by direct laryngoscopy or by bronchoscopy. The sudden onset of cyanosis with restlessness, especially if not explained by physical signs and particularly in the type of case considered an atypical bronchopneumonia, should call into consideration this disease.

The following two points may be worth further discussion: 1. Progressive and irreversible changes are caused early by laryngotracheal obstruction in the presence of infection so that relief must not be long delayed. 2. Postural drainage and irrigation are valuable measures which have not been fully appreciated in treatment.

In order to visualize the processes of this condition, to understand the varying picture and to judge how soon it may be necessary to intervene to prevent irreparable damage, it may be useful to review some of the experimental work on obstruction of the airway as well as that on the pathogenesis of acute pulmonary infections.

Since 1844 many observers have shown that atelectasis and emphysema can be produced by bronchial obstruction. Coryllos and Birnbaum[6] attempted to show that the important condition was prevention of the entrance of air and absorption of that remaining. Jackson and Manges[7] demonstrated that foreign bodies especially of the vegetal type might have the same effect. Galbraith and Steinberg's[8] experiments seem to show

that the essential factor is interference with respiratory movements due often to obstruction but often also to other causes which prevent inflation and deflation of the alveoli, leading to secondary vascular changes. The changes that they considered most important are congestion, stasis, edema and transudation.

Kernan and Barach [9] emphasized the importance of these circulatory effects and concluded that "as a result of the continued obstruction and the elevated negative pressure in the chest, blood enters the right chamber of the heart and lungs more freely but is retarded in its departure from the lungs into the left heart as a result of the backward suction pressure on the left ventricle as it delivers blood into the extrathoracic aorta. The elevated negative pressure within the chest exercises suction on the capillary walls, which is the important factor in the production of intra-alveolar exudate." They believe that air is absorbed with production of atelectasis and that emphysema comes from increasing distention of the alveoli during inspiration, with rupture of blood vessels and giving way of damaged alveolar wall. Increasingly greater respiratory effort keeps up a vicious circle.

For a clearer picture of what happens when infection is superimposed on these mechanical factors one may turn to recent work on the pathogenesis of pneumonia. Nungester and Jourdonais [10] were able to initiate pneumonia in dogs by introducing bacteria protected by mucin. Edema fluid carries from this focus multiplying bacteria. The spread from the primary infection, according to Loeschke [11] after many postmortem examinations of human material, is by gravity and by positive pressure of exudate in a lung that has negative pressure. According to Gunn,[12] spreading areas coalesce and, if bronchi are not blocked, the exudate flows into open alveoli of lobe or lobule and there are deposits of fibrin, leukocytic infiltration and the progressive changes of pneumonia.

If fibrinous plugs or infected exudate block a whole lobe there may be lobar pneumonia, which Coryllos and Birnbaum [13] considered really massive atelectasis with infection by pneumococci.

In view of the experiments of Galbraith and Steinberg [8] it seems also that, if there is much secretion and yet not enough to block all the bronchioles and so cut off the interlobular peripheral airways of Van Allen,[14] lobular pneumonia may result. If a plug blocks a bronchus or if so many of the bronchioles are blocked by thick secretion that the peripheral interlobular respiratory mechanism does not operate, one can think that absorption of air and atelectasis might occur early before the open alveoli can fill with exudate, with the picture as it is in acute laryngotracheobronchitis.

The bacteria present, the reaction of the tissue to them and especially the character of exudate or transudate produced may have much to do with the end result, as already stated with regard to lobar pneumonia. Reports vary widely as to the organism most common in tracheobronchitis, the hemolytic streptococcus usually being given first place. Bradford and Leahy [15] believe that the usual cultural methods allow this organism to overgrow. By a careful plating technic they showed in a series of thirty-six cases that green-forming streptococci were predominating and that most cultures ran less than 5 per cent of the hemolytic streptococcus. The tissue reaction to this organism seems perhaps more compatible with the usual observations.

A rather narrow margin of chance may determine the end result in certain cases of respiratory infection. It may be that when primary obstruction is late or incomplete, and exudate early invades open alveoli, the picture is one of lobar or lobular pneumonia. If there is primary obstruction with absorption of air or if the primary process causes the outpouring of thick secretion or fibrinous plugs to block regional bronchioles before the alveoli are infected, atelectasis occurs, usually with emphysema. If the patient survives, the train of results may be as noted by Galbraith and Steinberg [8] in experimental animals: atelectasis, pneumonitis, local necrosis, abscess formation, with later lung abscess or bronchiectasis.

That the picture may be a composite of these two types of process is evidenced by many clinical observations. Holt [16] observed that emphysema occurred in the majority of children dying of lobular pneumonia. Snow and Cassasas [17] observed roentgenologically in many cases resembling bronchopneumonia patchy atelectasis and emphysema with shifting roentgen and physical changes. They noted that the greatest involvement was in the dependent portions. It is observed that cyanosis in lobular pneumonia, especially of the influenzal type, may be of rather rapid onset and out of proportion to the physical changes.

This also would indicate that many of these cases might be amenable to the treatment to be outlined, although, as Jackson,[3] Gittins [2] and others emphasize, many cases considered bronchopneumonia must be laryngotracheobronchitis. It is interesting to note that Kernan [9] did bronchoscopic aspiration in lobar pneumonia with reported benefit.

It may perhaps be assumed, then, that the sequence of events in acute laryngotracheobronchitis is somewhat like this: An infection involves the larynx and subglottic tissues, and congestion and edema lead to nearly enough complete obstruction to raise the negative intrathoracic pressure, with added congestion, edema, exudate and capillary damage. Then thick secretion blocks bronchi or bronchioles whose walls are already swollen. As spreading secretion blocks the regional bronchioles, the interlobular tracts are cut off, air in the alveoli becomes absorbed, the dependent portions become atelectatic and the overlying ones become emphysematous. Infection and local circulatory changes add to the exudate, to absorption of air, to atelectasis and to emphysema and put out of commission more lung bed and further embarrass the heart. Cardiac and general exhaustion may here draw the final curtain.

The foregoing has been detailed to show that the problem is not one simply of blocked airway with anoxemia and perhaps sepsis and increased cardiac and respiratory effort and finally exhaustion but that the

process is much more complex. Grave secondary changes may at any time supervene and then any treatment may be unsuccessful.

In other words, the patient is likely to be saved early or not at all. This means that, if a trial of oxygen therapy and other measures does not give relief, tracheotomy is to be done without further delay. Cyanosis and rapid pulse are really late signs of imminent heart failure and must not be waited for.

In the condition herein discussed, bronchoscopic aspiration is often a necessary and life-saving procedure. As an adjunct, postural drainage seems to have been neglected, as there was no emphasis on its use in tracheobronchitis, even though mention is frequently made of the adverse effects of gravity on secretion. Postural treatment is widely used by chest surgeons and internists, but there is little about it in the medical literature.

Nelson [18] showed that even in bronchiectasis, in which sputum is viscid and tenacious, proper postural drainage was very effective and resulted in at least temporary cures. He insisted on the patient lying inverted with the hips over a double inclined plane, with the position maintained for days or even weeks with only very brief interruptions. Cures by it have been seen in early cases of bronchiectasis in children, and it is usually part of the medical routine in abscess of the lung.

One pediatrician [19] who sees many patients states that for a year he has treated influenza by postural drainage and has not had one case of pneumonia develop in such patients.

Postural drainage must be such that a real gradient is maintained from the main lower bronchial area to the trachea and larynx. According to Morlock [20] this should mean at least 15 degrees elevation of the foot of the bed, but better as much as the patient will tolerate, which will increase with use. In children the prone position with the foot of the bed raised provides a much better gradient and it is usually accepted easily.

Having in mind the physiopathology of acute laryngotracheobronchitis it would seem that here postural drainage would be especially valuable. The usual protective mechanism fails, secretion not being moved by cough, tussive squeeze or ciliary action. Secretion as it is first formed, whether as mucus, transudate, exudate or hemorrhage poured out in trachea, bronchi or bronchioles, must first be fluid and will flow some distance along the dependent wall before it forms plugs or crusts. At first at least ciliary action probably helps, and Leonard Hill [21] showed that cilia from the horse's trachea moved material twice as fast in the horizontal as in the vertical position. Murphy [22] injected into the bronchi of cats material of the viscosity of secretions found in asphyxia neonatorum and demonstrated that gravity drainage would clear the tracheobronchial tree.

If secretion can flow to the areas of greater cough reflex, tussive squeeze and cough will be much more effective. If any cough, squeeze or ciliary action is left, the help of gravity will be important. If secretion stagnates, it should be as a spread dependent layer and not as an occluding mass lying in a bronchial well. If plugs or crusts form, they will be nearer the outlet as we have observed bronchoscopically after instituting postural drainage and will be more likely to be expelled by cough, or will be more accessible to removal by aspiration or bronchoscopy.

Lavage of the respiratory tract has been proved feasible by Stitt [23] and by Minter,[24] the latter using as much as 400 cc. of fluid at a time in adults. Gittins [2] in tracheobronchitis used epinephrine and physiologic solution of sodium chloride in small amounts, aspirating it afterward. Richards [4] showed that solution of sodium bicarbonate tends to soften and dissolve plugs.

If one is to use fluid it would seem that after it is instilled the inverted posture should be used to guarantee its return and also to aid in the movement of secretion and plugs toward the tracheotomy opening. In recent cases from 4 to 15 cc. of from 3 to 5 per cent of warm solution of sodium bicarbonate at a time has been dropped into the tracheotomy tube with inspiration, usually with the gratifying result that it stirred up vigorous coughing, so that it was presumably drawn back and forth over crusts and plugs. This was carried out with the head elevated and the child turned toward the side on which the stethoscope indicated the greatest blocking. The head was then lowered and suction was used by a catheter through the tracheotomy tube. Physiologic solution of sodium chloride or Ringer's solution followed to wash out the sodium bicarbonate. Intermittently when there was much blocking epinephrine solution 1:10,000 was used; the stronger solution is known to produce undesirable secondary congestion in the nose. This treatment has proved of much value in recent cases, although it cannot supplant entirely bronchoscopic aspiration and forceps removal of crusts. It proved especially valuable in cases in which even a 3.5 mm. bronchoscope could not be passed. A capable intern can be trusted to use postural irrigation and save the laryngologist constant attendance and the patient tiring bronchoscopies.

SUMMARY

The treatment, briefly outlined, is as follows:

1. Rest—physical and mental—so that minimum oxygen is required.
2. No opiates or atropine.
3. Oxygen by tent, hood or catheter or into the tracheotomy tube. It is better given with helium with moderate positive pressure according to the principles of Kernan and Barach.[9]
4. Fluids by mouth and parenterally to relieve dehydration and increase fluidity of secretion.
5. Moisture-saturated air by croup tent.
6. Tracheotomy or, rarely, intubation; not delayed if the foregoing procedures do not soon give relief.
7. Postural drainage and aspiration.
8. Postural irrigation if secretion, plugs or crusts cause blocking.
9. Bronchoscopic removal of crusts if necessary.
10. Expectorants (?).

Of the ten patients who required cannulation in my service at the Evanston Hospital, two died. The cases were favorable because they were usually referred early by alert pediatricians, whose collaboration in the general care was invaluable. Some of these patients were seen every few hours day and night for four or five days, and no cases are included from a service of a larger charity hospital where I could not be in frequent attendance. In all it appeared certain that tracheotomy

FAILURES IN THE TREATMENT OF URINARY TRACT INFECTIONS WITH SULFANILAMIDE

EDGAR G. BALLENGER, M.D.
OMAR F. ELDER, M.D.
HAROLD P. McDONALD, M.D.
AND
REESE C. COLEMAN, M.D.
ATLANTA, GA.

Although introduced into clinical medicine less than five years ago, sulfanilamide has received abundant clinical trial. In adequate dosage the drug has already been proved to be most valuable in the treatment of infections caused by many organisms, especially the gonococcus and the beta hemolytic streptococcus. Why is it then that in some cases of such infections its use results in failure? Are the failures due primarily to resistance of individual strains of bacteria or are they due to some abnormality in the individual patient? Why are there such wide variations in the curative effects of sulfanilamide in cases of similar infections, perhaps even of the same strain?

In an attempt to answer these questions, we have undertaken the task of reviewing our failures in a fairly extensive use of sulfanilamide in urologic practice. In this study we include of course only infections ordinarily responsive to sulfanilamide and patients able to tolerate the drug in doses ordinarily effective and cooperative in other respects.

HOW DOES SULFANILAMIDE WORK?

The prompt control of many infections with sulfanilamide has aroused a decided revival of interests in chemotherapy and its mechanism. New concepts of man's fight against infection have arisen, and old ones are requiring many revisions. While there is still much to be learned about how this drug works, clinically sulfanilamide seems to produce three effects:

1. For certain organisms, notably the gonococcus, sulfanilamide has a definitely bactericidal effect in many cases.

2. Sometimes sulfanilamide merely limits the growth of the organism and does not eradicate it, the principal effect apparently being to prevent the extension of the infection to new regions.

3. Sometimes, however, sulfanilamide acts rather as an adjunct to the defensive mechanisms of the host.

It is not possible at this time to say definitely whether the effect of sulfanilamide is primarily on the susceptible organism or on the host's defensive mechanism. When sulfanilamide is diluted as much as it is in the blood stream, in vitro it appears to act as a bacteriostatic rather than as a bactericidal agent. The investigations of Long and Bliss [1] and others indicate that sulfanilamide acts in vivo by bringing about a change in the susceptible micro-organisms which permits phagocytosis. However, we are convinced that sulfanilamide also at times has a direct action in the fight against the gonococcus. For a number of years we have treated early gonorrhea in the male by sealing a 5 per cent solution of mild silver protein in the anterior urethra once daily for three or four days. Before the days of sulfanilamide this treatment was successful in obtaining a quick cure in from 15 to 20 per cent of suitable cases. With this treatment supplemented with sulfanilamide, this figure has now increased to 95 per cent, as already reported.[2]

Before the advent of sulfanilamide patients with gonorrhea were instructed to take fluids freely. This advice has been changed and now they are instructed to drink sparingly so as to obtain a higher concentration of the drug in the urine. As first determined by Helmholz [3] and confirmed by Farrell, Lyman and Youman,[4] when patients are taking sulfanilamide by mouth, sulfanilamide appears in the urine in sufficient concentration to be directly bactericidal. If the urethra is inflamed, patients are also instructed to void frequently in order to obtain the benefit of repeated flushing with urine containing sulfanilamide. This advice of course is reversed if toxic symptoms occur; then patients are urged to drink freely of water to hasten the elimination of the disturbing drug.

It should be noted that patients who discontinue the use of sulfanilamide too soon are apt to suffer a flare-up of the infection which often does not respond as well to a second course of sulfanilamide.

Numerous observers, however, have noted that better results were obtained in the treatment of gonorrhea when the use of sulfanilamide was started after the infection had been present for two weeks or longer.

Gaudin, Zide and Thompson [5] have observed that new organisms added at the time of transurethral prostatectomy were not killed as well by sulfanilamide as were bacteria present in the urine before the operation. They, like many others in England and in Europe, think that sulfanilamide stimulates some mechanism closely related to natural immunologic defenses.

In the clinical use of sulfanilamide it was soon observed that patients taking it did not have the usual percentage of troublesome prostatic infections. The reason for this was later explained by the experimental work on dogs by Farrell, Lyman and Youman,[4] who noted that sulfanilamide was eliminated in prostatic secretion in concentration high enough to be bactericidal.

Welsh, Wentworth and Mickle,[6] in a recent study of the infection which causes undulant fever, observed that the serum of patients or animals infected with Brucella organisms, when treated with sulfanilamide, was active in stimulating phagocytosis even after all the sulfanilamide had been excreted. The opsonic power toward Brucella of the blood of uninfected human beings or guinea pigs was not stimulated by sulfanilamide, a fact

which indicates that an infective or immunizing process must be in progress for the drug to stimulate phagocytosis in this disease.

On the basis of experimental work, Mellon, Locke and their associates [7] have concluded that the mechanism of the bacteriostatic action of sulfanilamide may be correlated tentatively with the host's resistance to infection. In numerous experiments they observed that "fitness" of the host is a prime factor in the eradication of the infection. When the temperature of rabbits is artificially lowered several degrees the animals exhibit great variations in the length of time required for their temperature to return to normal. This served as an index to "fitness," for those rabbits whose temperature returned to normal most quickly were most successful in combating pneumococci injected into the blood stream. They determined further that "fitness" may be increased by artificial fever, vitamin B_1, vitamin C, liver extract and adrenal cortex extract.

There appears then to be a relationship between the duration of the infection and the response to the sulfanilamide. While sulfanilamide is in some way effective in controlling the growth of many kinds of bacteria in vivo, it certainly involves other factors than the direct action of the drug on the bacteria.

SULFANILAMIDE WITH HYPERPYREXIA

Gonorrheal infections which were expected to yield to sulfanilamide but for some reason proved resistant without exception have been promptly benefited when the use of sulfanilamide was supplemented with artificial fever. We have also employed these two agencies simultaneously when for urgent business or domestic reasons an early cure of gonorrhea was essential. Patients whose physical condition was such that they could not be submitted to a major surgical operation with reasonable safety were regarded as unsuitable for artificial fever treatment. In suitable cases as a rule an oral temperature of 103 or 104 F. was maintained for three or four hours. When the pulse rate exceeded 140 the short wave current inducing the fever was discontinued regardless of the temperature obtained. These bouts of fever were given every other day until three or four had been administered. So used, artificial fever has proved safe and efficacious in reenforcing sulfanilamide therapy. It should be noted that in our work the patient's temperature is not carried to the thermal death point of the infecting micro-organisms and that the duration of the treatment is less than that usually recommended.

In our efforts to find other facts bearing on this subject, cultures of several types of organisms were subjected to (1) sulfanilamide alone, (2) heat alone and (3) the combination of these two remedies. The organisms employed in these tests were gonococci, streptococci, colon bacilli and staphylococci. There is, as is well known, a wide variation in the response of these organisms to germicidal agents and to heat. In our tests, however, the combination of the two agents was always more effective than either alone. This was found true whether the tests were carried merely to the point of bacteriostasis or to complete sterilization of cultures. While these tests in vitro showed that the combination was more efficacious than either alone, the results were never sufficiently good to explain the satisfactory clinical results with the combined treatment.

Why is this combination more effective than either agent employed alone? The answer seems to involve a number of factors: (1) those which concern the physiologic phenomena associated with the defense mechanism of the host, (2) those which concern the thermal sickening point or thermal death point of the infecting micro-organisms and (3) those which have to do with the concentration of sulfanilamide in the urine, blood stream, serum and tissues brought about by the profuse sweating incident to the artificial fever. In our investigations of this concentration we have noted in some instances that the level of sulfanilamide is increased in the blood as much as 25 per cent and in the urine from 35 to 50 per cent.

Our concept of the value of artificial fever has been supported in recent experimental work by Mellon.[7] Commenting on the reenforcement value of artificial fever in the treatment of rabbits having blood stream infections with type I pneumococci, he said that the removal of these organisms from the blood stream "was effected more rapidly in the sulfanilamide rabbits than in the controls; more rapidly still in those given artificial fever and with maximum rapidity in the rabbits given both fever and sulfanilamide."

In the combined attack on the infection, artificial fever appears to act like a call to arms. Body tissues, serum and cells seem to be placed on a war time basis, with defensive agencies mobilized and activated. Or the chemical attack with sulfanilamide followed with hyperpyrexia may be likened to the gas barrage which handicaps soldiers so that they are more readily overcome by the bayonet charge.

PROTECTED FOCI, OR DEAD SPACES

While sulfanilamide in combination with hyperpyrexia has given us prompter and more satisfactory results than we have ever seen before, these combined measures failed to cause a cure in about one case in ten. In searching for the explanation of our failures, we noted that in such cases we were usually able to discover a protected focus or what, for lack of a better term, we call a dead space. Among important potential dead spaces may be mentioned para-urethral crypts, periurethral follicles, prostatic and other abscesses, seminal vesicles distended with stagnant secretions, areas of urethral strictures, residual urine in the renal pelves and bladder, diverticula of the bladder, cavities surrounding calculi and foreign bodies, Skene's glands, Bartholin's glands, plugs of mucus in the uterine cervix, cervical crypts, areas of salpingitis, rectal or anal crypts, infected synovial fluid and regions from which lymphatic drainage is blocked. These dead spaces we are convinced usually are not reached by an adequate amount of blood laden with sulfanilamide and associated defensive agents manufactured by the host. They therefore continue to harbor the bacteria, though at times any of them may become free from infection without the application of special local measures.

In our use of sulfanilamide in combination with hyperpyrexia it gradually became evident that consistently good results could not be obtained unless pocketed infections, or dead spaces, were eliminated before curative bouts of fever were given or unless they received especial attention while the patient was in the fever cabinet. The eradication of such foci preparatory to the combination treatment often resulted in the clearing up of the infection without the use of fever therapy.

7. Mellon, R. R.; Gross, Paul, and Cooper, F. B.: Sulfanilamide Therapy of Bacterial Infections with Special Reference to Diseases Caused by Hemolytic Streptococci, Pneumococci, Meningococci and Gonococci, Springfield, Ill., Charles C. Thomas, Publishers, 1938.

For example, we may cite again "sealing treatment." Apparently the mild silver protein takes care of the dead spaces afforded by the mucus and secretion in the anterior part of the urethra and sulfanilamide kills or assists in killing the deeper infection if taken before the infection becomes protected in a pocketed area.

The eradication of dead spaces however, it should be emphasized, did not result in a cure by sulfanilamide when sulfanilamide was not adequate for the control of the major part of the infection. Such failures probably were due to the lack of an immunizing response on the part of the host.

The instances of protected foci of different types have convinced us that such dead spaces are prime factors in the resistance of gonococcic infections to sulfanilamide.

MEASURES FOR SPECIFIC FOCI

Of the methods of dealing with localized infections in dead spaces, perhaps the most valuable is the employment of local heat during the fever treatment as a supplementary measure. In the case of epididymitis this heat is applied to the epididymis; in the case of perifolliculitis, to the penis.

The acutely inflamed prostate, with perhaps multiple pocketed abscesses or cavities laden with stagnant secretion, unfortunately does not excrete sulfanilamide as does the normal gland. Therefore it not infrequently becomes desirable to treat such a prostate with local heat in addition to routine massage. In chronically infected seminal vesicles also stagnant secretion acts as a protected focus and should be emptied from time to time.

Protected foci not infrequently are associated with or caused by urethral strictures, which should be dilated.

Abscesses in any part of the genito-urinary tract require drainage and suitable treatment to prevent, if possible, the development of fistulous tracts. If a fistula already is present, it should be laid open or treated with a concentrated germicide.

Plugs of mucus in the uterine cervix may act as dead spaces. Adair and his co-workers have shown that this mucus contains very little sulfanilamide. For such areas there is need, therefore, for assisting measures. In the routine treatment of pelvic inflammatory disease we employ a prolonged hot douche of the Gellhorn type; this cannot, of course, be administered while the patient is in the fever cabinet. Vaginal bags of the Elliot or Mills type afford means of carrying heat to the cervix and pelvic organs during the period of hyperpyrexia. The heat from the vaginal bag causes an increase in the uterine and vaginal discharge. This secretion, fresh from blood and tissues bearing sulfanilamide, appears to be of distinct curative value. If such treatment is not effective, employment of the high frequency current or cautery may be required to eradicate endocervical foci.

Synovial fluid in inflamed joints should be aspirated. If it recurs, the effusion is then from serum and tissues containing sulfanilamide and the immunizing agencies stimulated by it. Inflamed joints require local heat in addition to sulfanilamide and fever therapy.

INFECTIONS OTHER THAN GONOCOCCIC AND TUBERCULOUS

Only a few remarks will be presented on the nonspecific infections of the bladder and kidney. Here protected foci play an important part in preventing the cure of ordinary genito-urinary infections. These dead spaces are different from those previously discussed; chronic and recurrent infections are practically always associated with obstructive lesions of the urethra, vesical neck or ureter. Control of the residual urine is the prime object whether the stagnating urine is in the bladder or the renal pelves. The constant contact of urine containing sulfanilamide with the lining of these cavities, however, often can overcome the infection in spite of the residual urine. This statement does not hold when calculi, retention catheters or other foreign bodies are present. Persisting infection or recurring infection always should arouse suspicion of the existence of obstruction, stones, diverticula or pocketed areas.

Sulfanilamide appears to control or to limit the infection associated with transurethral resection of obstructing prostates, but it usually does not clear the urine of infection until the healing is complete. Its use is not necessary or desirable during the entire convalescence or in large doses, but it may be employed intermittently and always cautiously, because elderly men with poor kidney function are likely to have toxic reactions. The fuzzy mucus-like coating over the resected area appears to act as a dead space. The same thing is true for the coating of ulcerating carcinomas of the bladder.

SUMMARY

We desire to emphasize again the importance of recognizing protected foci or dead spaces as chief causes of failure in the treatment of genito-urinary infections and to direct especial attention to the fact that a longer time, a higher degree of immunity or a greater concentration of therapeutic agents is required for the eradication of infection from such foci than for the eradication of infection not so protected.

Although sulfanilamide is a most efficacious drug, it is not one to be used indiscriminately or over prolonged periods without an effort to reinforce its use with supplementary measures or without a search for protected foci in need of special local treatment.

Our clinical experience has shown that hyperpyrexia is the most dependable agent with which to reinforce sulfanilamide in the treatment of resistant infections.

NOTE.—Since this paper was read, confirmation of our conclusions has been offered by J. S. Lockwood (Observations on the Mode of Action of Sulfanilamide and Its Application to Surgical Infections, *Ann. Surg.* **108**:801-812 [Nov.] 1938). Lockwood showed that even a small amount of peptone or of peptone-like products greatly retards the germicidal activity of sulfanilamide. As far back as 1911 Bainbridge had shown that some species of bacteria are unable to break down the protein molecule to obtain essential nitrogen. In consequence they starve to death in serum protein or egg albumin unless predigested protein in the form of peptone is supplied. Lockwood asserted that pus and tissue undergoing necrosis contain peptone-like products which prevent sulfanilamide from acting on the micro-organisms with the maximal effect that characterizes its effect on diffuse nonsuppurative infections. In a later paper (Studies on the Mechanism of the Action of Sulfanilamide, THE JOURNAL, Dec. 17, 1938, p. 2259) Lockwood and his associates stated that relapses "were frequent in patients with localized infections containing necrotic tissue, such as mastoiditis and abscesses, whereas in bacteremia and erysipelas they were not encountered." They asserted that "the presence of débris, human or bacterial, diminished the effectiveness of sulfanilamide on the hemolytic streptococcus."

METABOLISM OF THE BRAIN DURING INSULIN AND METRAZOL TREATMENTS OF SCHIZOPHRENIA

HAROLD E. HIMWICH, M.D.
KARL M. BOWMAN, M.D.
JOSEPH WORTIS, M.D.
AND
JOSEPH F. FAZEKAS
ALBANY, N. Y.

A previous communication[1] appearing in THE JOURNAL was concerned with the possible effects of insulin and metrazol in patients with schizophrenia. The conclusions were based on observations of animals, but methods were used which did not duplicate those employed in the treatment of schizophrenia. The present communication presents a brief summary of the chief results obtained in patients with schizophrenia undergoing the insulin and metrazol treatments. Since these treatments change cerebral function, studies of cerebral metabolism were made.

TABLE 1.—*Average Oxygen and Dextrose Differences Between Arterial and Venous Cerebral Blood*

Condition	Number of Observations	Oxygen, Vol per Cent	Dextrose, Mg per 100 Cc
Before injection of insulin	16	7.09	12.5
During hypoglycemic coma	26	3.07	4.16

The methods used for the study of the cerebral metabolism of the patients include the simultaneous collection of samples of arterial blood entering the brain and of the blood of the internal jugular vein, which represents the return flow from that organ. These samples are analyzed for oxygen and dextrose. The differences between the venous and arterial contents indicate the cerebral utilization of oxygen and dextrose.

Table 1 discloses the average differences of the oxygen and dextrose contents between arterial and venous samples before the injection of insulin and during the hypoglycemic coma. The utilization of oxygen is diminished during coma from 7.09 volumes per cent to 3.07 volumes per cent. Assuming a constant blood flow, this indicates a diminished metabolism of the brain of about 55 per cent. However in hypoglycemia, according to Loman and Myerson,[3] the blood flow may be diminished, and the decrease of metabolism is therefore probably even greater than that indicated by the arteriovenous differences.

Thus the depressed cerebral metabolism and the coma are the direct results of the absence of carbohydrate, as the blood sugar diminishes in response to the injection of insulin. The brain, unlike other organs, oxidizes practically only one foodstuff, carbohydrate,[4] and as the available carbohydrate decreases the metabolism of the brain must necessarily diminish.[5] It should be pointed out, however, that during hypoglycemia the brain does not suffer from lack of oxygen. On the contrary, the oxygen content of the brain may rise, owing to the diminished utilization of that gas.

On the other hand, anoxia is developed during convulsions induced with metrazol,[6] for convulsions interfere with respiratory movements. Since it is physically impossible to draw blood from the internal jugular vein during the convulsions, only arterial samples were collected at this time. Table 2 discloses that during various stages of the convulsions the oxygen saturation of the hemoglobin of the arterial blood may decrease to 42 per cent, less than half the normal saturation of approximately 95 per cent. It is noteworthy that in these cases a moderate rise of blood sugar was noted after the initiation of the seizure. Even in the first moments after the convulsions are ended the oxygen saturation of the arterial blood does not attain normal values. Convulsions interfere temporarily with the oxygenation of the blood and therefore of the brain, thus diminishing cerebral metabolism. To contrast the fundamental differences of the actions of metrazol and insulin, the latter decreases the amount of coal (dextrose) necessary for the fire to support cerebral functions, while metrazol interferes with the draft (oxygen) required to maintain the flame. The end results, in regard to the supply of energy to the brain, are the same with the two methods.

Sakel[7] has reported that if convulsions occur during insulin hypoglycemia a dramatic improvement of the patient may be observed. Because of this fact he considers it advantageous sometimes to provoke convulsions by the injection of metrazol during hypoglycemia. It is significant that anoxia is produced by convulsions

TABLE 2.—*Percentage Hemoglobin Saturation of Arterial Blood During and Immediately After Metrazol Convulsions*

Patient	Oxygen Content, Vol per Cent	Oxygen Capacity, Vol per Cent	Hemoglobin, per Cent	Blood Drawn in Regard to Duration of Seizure
Wi	18.97	22.62	84	First half
M	8.70	20.64	42	Late

Wa	20.43	22.71	90	

irrespective of the level of the blood sugar. For example, with convulsions occurring in response to low blood sugar (11 mg. per hundred cubic centimeters) an arterial hemoglobin saturation of 63 per cent was observed, while convulsions induced by metrazol during hypoglycemia resulted in a saturation of 61 per cent as blood sugar rose from 26 to 37 mg. per hundred cubic centimeters.

This work was aided by a grant from the Child Neurology Research (Friedsam Foundation).

Thus convulsions occurring during hypoglycemia add to the effects of hypoglycemia those of anoxia and therefore involve both methods of diminishing the metabolism of the brain. This synergism permits the simultaneous utilization of the more prolonged action of insulin and the more severe one of metrazol. Though it is improbable that this diminished metabolism of the brain is the only factor involved, this review of the results obtained on patients with schizophrenia suggests that a depression of cerebral metabolism is associated with the initiation of the changes which lead to the amelioration of the disease. On this basis, patients with schizophrenia are now being treated with acute anoxia produced by the inhalation of nitrogen.[8]

Clinical Notes, Suggestions and New Instruments

VIRILISM IN WOMEN CAUSED BY ANDROGENIC THERAPY FOR MENSTRUAL DISTURBANCES

J. P. GREENHILL, M.D., AND S. C. FREED, M.D., CHICAGO

An interesting phase of the endocrine therapy of gynecologic conditions has recently arisen with the introduction of testosterone propionate, an androgenic substance, in the treatment of certain menstrual disorders. Desmarest and Capitain,[1] Loeser,[2] Foss[3] and others have shown that this substance in doses varying from 400 to 2,000 mg. a month is capable of suppressing abnormal uterine bleeding. Loeser[2] has shown that at least 500 mg. of testosterone propionate must be given to suppress normal menstruation. It has also been reported that beneficial results may be obtained with smaller doses in cases of painful breasts and dysmenorrhea. The use of testosterone propionate in these conditions was suggested by its similarity in action to progesterone. In the rat and rabbit a progestational-like state of the endometrium was induced by administration of this substance. Furthermore, this androgen is capable of suppressing sex cycles of several species, inhibiting uterine contractions, neutralizing the action of estrogen on the vaginal mucosa and suppressing menstruation in monkeys and human beings, reactions which are typical of progesterone.

With the publication of the preliminary clinical reports on the use of testosterone propionate, a considerable wave of enthusiasm arose for the use of this substance in menstrual dysfunctions. The following report of two cases in which this substance was used is presented to deter physicians from the promiscuous use of androgenic therapy in females. The disagreeable side effects we have obtained with such therapy have definitely cooled our initial ardor, and, it is hoped, may serve as a warning to others.

REPORT OF CASES

CASE 1.—Mrs. A. F., aged 26, had been married six years and had never been pregnant. She consulted one of us (J. P. G.) Nov. 30, 1936, because of severe dysmenorrhea, which had been present since the onset of menstruation at the age of 13. This pain was so severe that the patient had to go to bed for two days every month. The monthly flow was profuse and at times alarming. After having tried numerous remedies the patient for a long time had used a combination of large doses of narcotics and a liberal quantity of whisky. The patient had had an appendectomy in 1935, and this failed to influence the menstrual pains.

Physical examination revealed that the head, neck, chest and abdomen were normal. Bimanual examination showed a nulliparous outlet, a slightly eroded cervix, a small, hard, anteflexed and movable uterus and normal adnexa. The Rubin test revealed patent tubes. The basal metabolic rate was —14 per cent, and biopsy just before menstruation revealed the endometrium in the late secretory stage. Hence ovulation was present.

Dilation and curettement were performed in the hope of giving some relief from the dysmenorrhea. The endometrium showed normal secretory epithelium. During the next five months the patient was almost free from pain at the time of the menses. Then the pain returned and at the same time the flow of blood became more and more profuse. Furthermore the menstrual periods lasted from ten to thirteen days instead of four or five days. April 30, 1938, menstruation was so profuse that the patient had to be taken to a hospital. At this time the basal rate was again —14 per cent. Before and after this episode various forms of medication had been given in an attempt to control the menorrhagia. These included thyroid, anterior pituitary-like substance, snake venom, solution of posterior pituitary, ergonovine and solution of parathyroid and calcium. Repeated bimanual examinations during all this time failed to reveal any abnormalities.

In June it was decided to try large doses of estradiol benzoate. The patient was given 10,000 rat units twice during the first week following her menstrual period and 2,000 rat units twice during the second week. This medication had no effect on the following menstrual flow, which was as profuse and as painful as the previous ones. It was then decided to give the patient testosterone propionate. The menstrual period had begun July 13. The patient was given 50 mg. of testosterone propionate July 18 and July 19, 100 mg. July 20, 22, 25, 27 and 29 and August 1 and 2 and 50 mg. August 5, a total of 850 mg. in nineteen days. A vaginal smear and a biopsy specimen were taken August 8, two days before the menstrual period was expected. The vaginal smear showed a decrease in the number of cornified cells. The biopsy revealed that the endometrium was in the follicular phase, in spite of the fact that the menses were to occur two days later.

August 23 the patient complained of an acneform rash on the chest, a large amount of hair on the upper lip and increase in weight. The menses, which had been due August 10, did not begin until August 29, nineteen days later. This period was just as painful as before.

It was decided to give a second course of treatment with testosterone propionate. The patient was given 50 mg. September 9, 12, 14, 16, 19, 21, 23 and 26 and 25 mg. September 28 and 30, a total of 450 mg. in twenty-two days. September 30 the patient complained bitterly that the hairs on the upper lip were rapidly increasing in number, length and darkness and that considerable hair was growing on her arms and legs. Likewise her voice was husky and her friends had been asking her about this. The weight had increased 10 pounds (4.5 Kg.) in spite of attempts to diet rigidly. The acne reappeared and was present not only on the chest but on the back. There had been a definite decrease in the size of the breasts. October 10 examination showed a distinct enlargement of the clitoris. This organ was reddened, as was the skin immediately surrounding it.

Menstruation did not return until November 1, an interval of sixty-four days having elapsed since the previous menses (August 29). The menses were painless and the flow was slight. The patient stated that she felt better than she had for more than a year. However, she still has her excess weight, hirsutism, acne and deep voice. The basal metabolic rate November 15 was +3 per cent. Bimanual examination revealed nothing abnormal. However, the clitoris was definitely smaller and there was no redness on or around it.

CASE 2.—Mrs. S. H., aged 22, came to see one of us (J. P. G.) Nov. 11, 1936, for premarital examination and advice. The past history was irrelevant, and the only abnormality in the menstrual history was severe dysmenorrhea. Rectal examination revealed large hemorrhoids and a fibroid on the right side of the uterus, which measured approximately 5 cm. in diameter. April 2, 1937, a few months after marriage, the fibroid appeared to be about 6 or 7 cm. in diameter. A discussion was had concerning the advisability of removing the fibroid, both because of the possibility that it was causing the

severe dysmenorrhea and because it might be better to remove the mass before the patient became pregnant.

Because of the patient's youth and the desire to wait for children, nothing was done. In July 1938 it was decided to give testosterone propionate and note its effect on the fibroid and the dysmenorrhea. A biopsy revealed an early proliferative stage of the endometrium. The menses began August 7. The patient was given 50 mg. of testosterone propionate August 15, 17, 19, 22, 24, 26, 29 and 31, September 2, 7, 9, 12 and 14, 25 mg. on September 16, 19, 21, 23, 26 and 28 and October 3 and 7, a total of 850 mg. in fifty-three days. On August 26 a biopsy specimen was taken. This showed an early proliferative phase.

August 28, thirteen days after the administration of testosterone propionate was started, a menstrual period began, and the patient had no pain at all (after 300 mg. of testosterone propionate). This period started seven days early. However, this bleeding began two days after the biopsy specimen was taken and may not have been a menstrual period. August 29 the patient complained that she had gained 6 pounds (2.7 Kg.) (after 300 mg. of the substance). September 16, bimanual examination showed that the fibroid was distinctly smaller, only about 4 cm. in diameter (after 650 mg.). Another biopsy specimen obtained on this day showed an early proliferative phase of the the endometrium. On September 19 the patient complained of an annoying acneform eruption on her face and arms. The weight was still increasing in spite of strenuous dieting. Furthermore, the patient's husband had been noticing a steadily increasing hoarseness in the patient's voice for more than a week. This continued to increase in severity until the voice sounded almost like a man's, especially over the telephone. Another biopsy specimen taken October 12 showed the follicular phase of the endometrium. November 2 the patient complained not only of persistent huskiness of the voice, acne and increase in weight but also of an abundant growth of hair on the upper lip and on the chin.

Bimanual examination November 7 revealed that the fibroid had increased in size again, almost to the size it was before the testosterone propionate was administered. The menses did not return until November 18, eighty-two days after the last menses (August 28). The deep voice, excessive hair and overweight were still present, but the acne had cleared considerably. The menstrual pains were about 50 per cent less than usual, but the amount of blood lost was much greater than usual. Bimanual examination November 23 showed the same condition as on November 7.

COMMENT AND CONCLUSION

An analysis of these cases reveals that testosterone propionate in doses which are effective therapeutically is potent in the induction of a significant degree of virilism. Growth of hair on the face and body was stimulated and a lowering of the voice to a masculine pitch was obtained in both cases. Enlargement of the clitoris, however, was observed in only one. It was first expected that these masculine developments would regress soon after the cessation of injections. The clitoris in the one case has returned to normal, but the hirsutism and male voice have persisted to the present time, eight weeks after the last injection of testosterone propionate. It should be noted that menstruation has returned in both cases and the fibroid uterus regained its normal size in the one case, indicating that ovarian function has returned without the disappearance of the virilism. The possibility that these changes may eventually vanish is still present,[3a] but it is significant that with the removal of the masculinizing ovarian tumor, the arrhenoblastoma, the masculine voice persists, indicating that a similar result might be expected, by analogy, with the masculine voice induced by administration of androgenic substances.

Other disagreeable reactions were acne and increase in weight. This tendency to gain weight has been noted frequently in male castrates treated with androgen by Kenyon.[4] This effect was noted in one of our patients in spite of an increase in the basal metabolic rate.

It is true that a certain therapeutic response was obtained. Intractable menorrhagia and dysmenorrhea were controlled in the first case, temporarily at least, by androgenic therapy. Dysmenorrhea associated with a fibroid of the uterus was checked in the second case in that the menses were inhibited. A definite decrease in the size of the fibroid was probably the result of the inhibition of ovarian function by androgen, similar to that noted in monkeys by Zuckerman[5] and in rats by the work of the Mazers[6] and by Freed, Greenhill and Soskin.[7] This explanation is confirmed by the observation in endometrial biopsies that ovulation was prevented in both cases.

It is questionable, however, whether the beneficial results noted in our cases were worth the concomitant undesirable side reactions. Further observations are of course necessary to justify more definite conclusions. At present we are of the opinion that androgenic therapy in women should be approached with caution and is not to be recommended until the danger of virilism can be eliminated or controlled. It is not unlikely that an androgen or similar substance may be developed which will possess the desirable therapeutic effects of testosterone propionate without the harmful virilizing effects.

55 East Washington Street.

3a. In case 2 practically all the symptoms of virilism disappeared about January 10, three months after the last injection of testosterone dipropionate. In case 1 the huskiness and hirsutism are still present, almost four months after the last injection.

CHRONIC ULCER OF THE LEG ASSOCIATED WITH CONGENITAL HEMOLYTIC JAUNDICE

EARL S. TAYLOR, M.D., NEW YORK

Since the beginning of the century a considerable literature has accumulated concerning hemolytic jaundice. In 1900 Minkowski and later Chauffard described the congenital type, and between 1907 and 1911 Hayem Widal and his associates presented a group which they considered to be "acquired." Attention was first called to the disease in this country by Tileston and Griffin[1] in 1910. Subsequently the excellent studies of Gänsslen,[2] Eppinger[3] and Meulengracht[4] completed the clinical picture of the disease as it is known today. Dawson[5] and others have presented considerable evidence to show that the acquired and the congenital types are closely related and have cast considerable doubt as to whether any cases that rightfully belong to this group are actually "acquired." Haden's[6] work demonstrated that the spherical microcyte is the fundamental variation from the normal in this disease and that "the anemia, jaundice, splenomegaly, reticulocytosis and increased fragility are all secondary to the globular form of the erythrocyte." An excellent summary of the clinical and laboratory appearances of the disease was given by the Cheneys[7] in 1934.

Aside from the anemia, the commonest complication of the disease is probably gallstones, occurring in 68.6 per cent of the cases reported from the Mayo Clinic.[8] Skeletal defects ("tower skull" of Gänsslen, and the like), joint pains and nosebleeds are also well known associated happenings. In the standard medical textbooks and in a number of the monographs no mention is made of chronic ulceration of the leg as a complication. Gänsslen[2] was one of the first to note this condition and its permanent regression obtained by splenectomy, although he disavows priority in calling attention to it.[9]

REPORT OF CASE

The following case is of interest in this respect, and it will be noted that the presence of chronic ulceration of the leg was the patient's presenting symptom.

F. M. H., a woman aged 20, of German-American parentage, an unemployed stenographer, admitted to Vanderbilt Clinic June 29, 1937, complained of a chronic sore on the inner side of the left ankle of twelve months' duration About one year before she had struck her ankle on a store counter. A bluish spot appeared, and three weeks later a "hole" developed. The lesion was quite painful and interfered with weight bearing but not with motion. She had been treated intermittently at several clinics with ultraviolet rays, boric acid ointment dressings and the like, with little or no progress. Examination of the lesion showed a shallow ulceration 1 by 2 5 cm just above and posterior to the internal malleolus. There was a moderate amount of yellow slough. A dusky cyanosis surrounded the ulcer for an area of 5 by 6 cm An area 2 by 3 cm of this same dusky hue without ulceration was present in a similar location on the right ankle. X-ray examination of the ankle joint was negative. Aerobic and anaerobic cultures yielded only Staphylococcus aureus. The Wassermann reaction was negative. There was no history or clinical condition to suggest tuberculosis. An "elastoplast" bandage was applied, but irritation of the skin was so marked that it could not be tolerated On her visit July 14 an icteric tint of the sclerae and skin was noted. Abdominal examination revealed the spleen palpable four fingerbreadths beneath the left costal margin Further history revealed that the patient's mother had been "yellow skinned and bruised easily." She was said to have died at 51 from "heart disease." The patient had been at another hospital three years previously because of pain in the left upper quadrant. The enlarged spleen was noted and removal was advised, but the patient refused operation. The patient was admitted to the Presbyterian Hospital July 18. Examination of the blood revealed hemoglobin 60 per cent, red blood cells 3,200,000, white blood cells 7,400, with platelets 317,000, reticulocytes 23.9 per cent, polymorphonuclear leukocytes 58 per cent (0-4-54), eosinophils 5 per cent, basophils 1 per cent, lymphocytes 32 per cent, monocytes 4 per cent, nucleated red cells 1/100, bleeding time two and one-half minutes, clotting time two minutes and forty-five seconds. The red blood cells showed marked anisocytosis

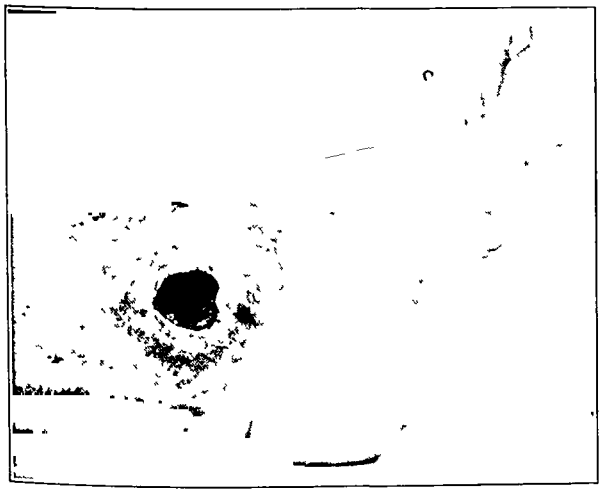

Fig 1.—The shallow indolent ulcer before operation Note the surrounding area of dusky cyanosis and pigmentation of the skin.

with a tendency to microcytosis, 19 per cent being the typical spherical microcytes of hemolytic jaundice. Fragility began at 0 625 per cent and was complete at 0.35 per cent The range of the control was between 0 425 and 0 3 per cent, serum bilirubin 4.4, urine bile 0, urobilin positive. Figure 1 shows the ulcer of the leg July 21 before operation

Splenectomy was performed by Dr. Louis M. Rousselot July 23. A thin walled gallbladder without stones was noted The postoperative course was uneventful except for an unexplained elevation of temperature on the third postoperative day. The pathologic examination of the spleen by Dr. V. K. Frantz revealed hemolytic jaundice. The spleen measured 19 by 14 by 8 cm. and weighed 760 Gm. A thin shiny capsule stripped easily. The cut surface was dark red and did not bulge beyond the capsule The outstanding feature on section was the mass of closely packed red corpuscles throughout the pulp, even infiltrating into the malphigian bodies. The venous sinuses were

Fig 2.—The site of the ulcer has remained healed nine months after operation but the pigmentation of the skin is still present

large. There was no fibrosis A few hemosiderin-laden phagocytes were noted. These observations correspond to those which Thompson[10] has described as the typical and constant pathologic picture found in the spleen in true hemolytic jaundice.

The patient was discharged sixteen days after operation with the ulcer of the leg healed and with a firm abdominal wound The blood examination revealed hemoglobin 83 per cent, red blood cells 4,000,000, white blood cells 5,400, platelets 189,000, reticulocytes 0 2 per cent, polymorphonuclear leukocytes 41 (0-1-40) per cent, eosinophils 4 per cent, basophils 2 per cent, lymphocytes 39 per cent, monocytes 4 per cent. The patient was last seen April 30, 1938, nine months after the operation, and stated that she had "never felt better" in her life. The ulcer has remained healed (fig. 2).

COMMENT

This is the first patient with this complication who has been seen in the Spleen Clinic at Presbyterian Hospital, where forty-three patients both with and without splenectomy have been carefully followed for a number of years. Undoubtedly, chronic ulceration of the leg is an infrequent finding in this disease, for Meulengracht in his careful study of thirty-four cases makes no mention of it

In reviewing the literature at least seventeen similar cases[11] are found and recognition of this complication is made by a number of authors, particularly in Germany and the Scandinavian countries.[12] The large majority of the patients are young women in the second and third decades of life and give a history of having had persistent or recurrent ulceration of the lower leg for from two months to twenty years.

Treatment with ointments, wet dressings and bed rest for as long as two months is only rarely successful, and recurrence is the rule. Three of Eppinger's patients had persistent or

recurring lesions of from seven to twenty years' duration. In a case [13] in which splenectomy was refused, healing was reported after the patient was in bed three months with boric acid ointment dressings, but no follow-up is given.

In the twelve cases in which splenectomy was performed, all the resistant lesions healed in from eight to thirty days. One lesion [14] recurred following direct trauma but healed promptly and showed no evidence of recurrence three and one-half years later.[15] Another [3] had some oozing with each menstrual period for a year and a half after the operation but it finally healed.

Splenectomy in this disease is now a relatively safe procedure. Large series of collected cases show a hospital mortality of but from 3 to 4 per cent.[16]

Even if operation appears to be mandatory during an acute crisis, the mortality is probably not appreciably higher in competent hands.[17]

The ulcers are almost always located in the region of the medial malleolus. There is usually only a single ulcer on the leg, but in about half of the cases there is bilateral involvement. Occasionally multiple ulcers are found in cases of long standing.[14]

Trauma may or may not precede the appearance of the ulcer. Frequently a dusky blue area in the region of the medial malleolus is the first manifestation of the impending ulceration. This breaks down in the center and a shallow indolent erosion appears, which advances to about 3 to 5 cm. in diameter. Larger punched out lesions appear only in the cases of very long standing. There is a moderate amount of yellowish slough. The edges are only slightly elevated and there is little undermining. A ring of the bluish cyanosis or dark pigmentation circumscribes the lesion. There is often considerable pain and, although limitation of motion is unusual, weight bearing may be considerably compromised.

Since Gänsslen's early report there has been considerable speculation as to the nature of the mechanism that causes these lesions to appear and as to why there is prompt permanent remission following splenectomy.

It has been suggested that the ulcers are just another of the congenital defects [2] associated with the disease. This is obviously inadequate, for all the other structural defects remain after clinical cure of the disease is accomplished by splenectomy. The possibility of an effect on the walls of the capillaries secondary to some of the abnormalities found in the chemical analysis of the blood has also been mentioned as predisposing to these ulcers. This seems unlikely, for at no time during the course of the disease can any increased capillary fragility be demonstrated.[18] Similarly, the spherical microcyte itself cannot be considered a causative agent, for it persists following operation long after the lesions have healed.

At present there is no satisfactory explanation of this phenomenon. It is interesting to note that in sickle cell anemia, which has many points of similarity to congenital hemolytic jaundice, three out of four patients reaching adult life have ulceration of the leg.[19] It would seem suggestive then that the causative agent will be found to be a factor common to the two diseases.

SUMMARY

Chronic ulceration of one or both medial malleolar regions occurs as a complication of congenital hemolytic jaundice. The lesions are highly resistant to all local therapy, but splenectomy affords a rapid, permanent cure.

Little recognition is accorded this complication, particularly in this country. It is undoubtedly an infrequent finding but may be the only manifestation of the disease that brings the patient to seek medical aid.

The presence of these ulcers is an added indication for splenectomy if they interfere with the patient's ability to work.

In the presence of apparently unexplained chronic ulceration of the leg, particularly in a young white woman, investigation of the morphology and fragility of the red cells should be made.

PRIMARY ADENOCARCINOMA OF THE JEJUNUM WITH PERFORATION

REPORT OF A CASE WITH SOME CLINICOPATHOLOGIC NOTATIONS

EDWARD A. CHRISTOFFERSON, M.D.
Attending Surgeon, Cook County Hospital
AND
MAURICE B. JACOBS, M.D.
Department of Pathology, Cook County Hospital
CHICAGO

Carcinoma of the jejunum, like carcinoma of the rest of the small intestine, is rare. Acute perforation of such a lesion is still more unusual. Carter [1] in 1935 mentioned that perforation of such a growth with peritonitis was recorded in only one case of laparotomy in the preceding eight years. No doubt he had reference to the case reported by Dencks,[2] which will be described later and which is the only instance of involvement similar to that to be reported that we have been able to find in the literature. The case here reported presented clinically the picture of perforated peptic ulcer.

REPORT OF CASE

History.—J. K., a white man aged 48, a laborer, admitted May 1, 1935, to the Cook County Hospital (surgical service of Dr. John Harger), was seized suddenly with severe pain in the abdomen twenty-two hours before admittance, while doing some repairs on a house. The pain was described as cramplike and more severe in the lower part of the abdomen. It was

Fig. 1.—Surgical specimen, showing broad perforation in the tumor of the jejunum.

of such intensity that he was forced to lie down immediately. After an hour it ceased and he resumed work. An hour later, however, the pains recurred, increasingly severe and constant. At 5 a. m. (seventeen hours after the onset) a physician advised hospitalization; at this time there was also pain referred to the right shoulder.

The past medical history was entirely irrelevant except for constipation. He took alcohol occasionally. There had been no selective dyspepsia, epigastric distress, loss of weight or vomiting.

On admission the temperature was 100.6 F. rectally, the pulse rate 102, the respiratory rate 36 and the blood pressure 132 systolic and 80 diastolic.

The essential physical pathologic changes were limited to the abdomen and consisted of diffuse boardlike rigidity, slight dis-

tention and diffuse tenderness. Rebound tenderness was elicited in the left lower quadrant and on auscultation the peristaltic sounds were absent, but there was an occasional metallic click

Fluoroscopic examination by Dr. R. T. Vaughan revealed free air under the right dome of the diaphragm. Examination of the urine gave negative results; the white blood cell count

Fig. 2.—Section taken near the perforation, under low power, showing invasion of the muscularis by the tumor glands Hematoxylin and eosin stain.

was 7,800 per cubic millimeter. A preoperative diagnosis of perforated peptic ulcer was made.

Operation and Result.—Operation was performed (by E. A. C.) four hours after admission to the hospital and twenty-six hours after the onset of the initial pain. The abdomen was opened through a right paramedian epigastric incision. The intestinal loops were distended and a considerable amount of bile-stained seropurulent exudate was present. Examination of the stomach, duodenum, gallbladder and appendix, however, revealed no perforation. It was only after following the stream of exudate to its source below the transverse colon and omentum that the perforation was found in the jejunum. The perforation was fully 2 cm. in diameter and occupied the center of a firm constricting mass in this portion of bowel, 18 inches distal to the ligament of Treitz. Intestinal contents were escaping freely The regional mesenteric lymph glands were enlarged and firm

A diagnosis of probable carcinoma was made, and a wide resection of this area together with its mesentery was done The continuity of the bowel was restored by an end to end anastomosis.

Course.—The patient did fairly well until the third postoperative day, when the wound began draining seropurulent material The abdomen became distended and the peristaltic silence persisted. On the following day, four days after admission to the hospital and five days after onset, the patient died.

Surgical Pathologic Examination (Dr J D. Kirshbaum).—Gross: The specimen submitted consisted of a portion of jejunum 14 cm. in length, in the center of which was an ovoid defect measuring 3 by 1.5 cm. involving the entire thickness of the wall. The edges of the defect were firm, irregular and slightly rolled. The serosa was discolored purple-red, the mucosa was purple-tan and edematous (fig. 1).

Microscopic: Sections taken from the region of the tumor revealed a much thickened mucosa, heavily infiltrated with round cells and polymorphonuclear leukocytes. The crypts were lined by tall epithelium and in places were two and three layers thick. Their nuclei were irregular and hyperchromatic, atypical mitotic figures being frequently seen. In places the mucosa was thrown into folds assuming a polypoid appearance. In one area the mucosa was missing and the floor of the defect was formed by the muscularis propria. Beginning at the surface there were dilated and elongated glandlike crypts lined by anaplastic tumor cells. They invaded the entire muscularis propria and extended to the serosa. There was no tendency to production of mucus. In the region of the intact mucosa the tumor glands were seen to extend radially. There were marked thickening in the subserosa distal to the tumor and dense infiltrations of round cells, plasma cells, large mononuclear cells and polymorphonuclear leukocytes (figs. 2 and 3). The diagnosis was adenocarcinoma of the jejunum with ulceration and perforation.

Necropsy—This was performed six hours after death by Dr. B. Nieman. The essential pathologic observations were restricted to the abdomen. The intestinal loops were markedly distended by gas and were plastered together by loose fibrinous membranes. The serosa was dull and injected; the omentum was adherent to the anterior part of the abdominal wall. Examination of the entero-anastomosis with water revealed no defect in the line of suture. The mesenteric and periaortic lymph glands measured up to 25 mm. in diameter and on sectioning were yellow-gray. The lungs presented areas of focal pneumonia in both lower lobes.

Microscopic Examination of the Periaortic Lymph Node (Dr. Richard Jaffé) (fig. 4) · The normal architecture of the lymph node was discernible only at the periphery. The greater portion of it was replaced by nests of glandular epithelium which resembled intestinal mucosa. The glands were round to oval and were lined by cuboidal to columnar cells. Their nuclei were anaplastic, occasional mitotic figures being seen. In between the tumor glands there was a moderate amount of cellular stroma.

The anatomic diagnosis was recent laparotomy wound for resection of a portion of the jejunum, diffuse fibrinoplastic peritonitis, pseudomembranous enteritis, end to end entero-

anastomosis of the jejunum, metastases of adenocarcinoma to the mesenteric and periaortic lymph nodes and aspiration bronchopneumonia of both lower pulmonary lobes

COMMENT

We have been able to find only one case of similar involvement in the literature, namely, that reported by Dencks,[2] of a 42 year old man who complained of sudden, severe abdominal pain two hours after the noon meal. A physician administered

morphine. On the following day the patient was admitted to the hospital with symptoms of perforative peritonitis of about ten hours' duration. A laparotomy was performed immediately and a small annular stenosing tumor was found with a perforation at the mesenteric border. A wide resection of this area with an end to end anastomosis was performed and the patient made an uneventful recovery. Histologically the tumor proved to be a cylindric cell carcinoma of glandular type.

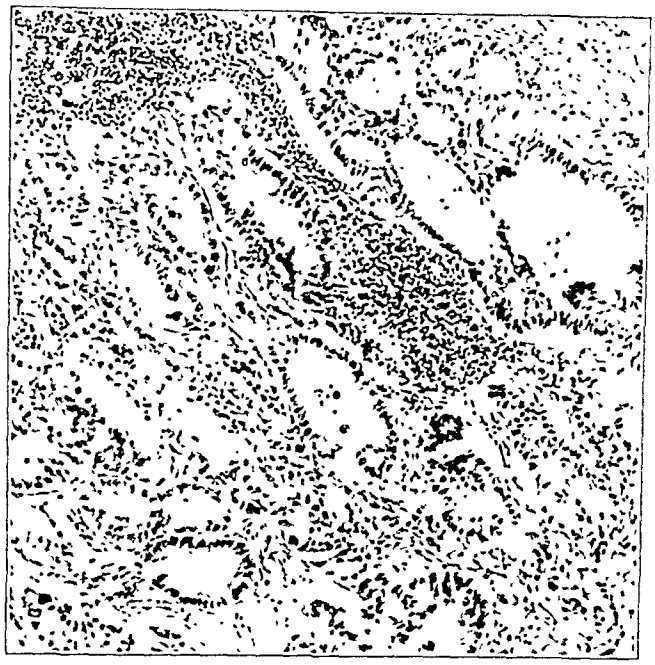

Fig. 4.—Section under low power from one of the periaortic lymph nodes, showing metastasis. Hematoxylin and eosin stain

Keyser [3] in 1908 reported jejunal carcinoma with fatal perforative peritonitis in a patient in whom a previous exploratory laparotomy had shown an inoperable tumor.

From the statistical study given in the table it will be seen that carcinoma of the small bowel is relatively rare and occurs with least frequency in the jejunum. Because of this rarity there is some discrepancy in the reported incidence of carcinoma of the small intestine from the various clinics. Ewing [4] stated that carcinoma of the small bowel forms 3 per cent of all intestinal carcinomas. Mayo and Nattrour,[5] in reviewing seventy-six cases of carcinoma of the small intestine observed at the Mayo Clinic in the ten years prior to 1936, found that carcinoma of the small bowel comprised 0.62 per cent of all the carcinomas from the cardiac end of the stomach down to and including the rectum, and that carcinoma of the jejunum formed only 0.15 per cent of all the carcinomas of the gastrointestinal tract.

A review of 10,309 necropsies performed at the Cook County Hospital during the nine years from 1929 to 1938 showed seven cases of carcinoma of the small intestine, three of the duodenum and four of the jejunum, compared to 273 cases of carcinoma of the stomach and 163 cases of carcinoma of the colon and rectum—a frequency of 1.6 per cent for carcinoma of the small bowel and 0.9 per cent for jejunal carcinoma among carcinomas of the gastrointestinal tract.

Many theories have been proposed for the relative infrequency of carcinoma of the small intestine, among which may be mentioned the embryonic rest theory of Cohnheim. Other authors have attributed the low incidence to the absence of abrupt bends and irritation such as is seen in the sigmoid colon, the rectum, the hepatic and splenic flexures and the cecum. Carcinoma of the intestinal tract is found at points where there is an abrupt change in the lining epithelium of the canal, e. g. at the junction of the esophagus and the stomach or at the anus and rectum. These abrupt changes are absent in the small intestine. Rankin and Mayo [6] subscribe to the theory that the fluid nature and the alkaline reaction of the contents of the small intestine may explain the lowered incidence of carcinoma of the small bowel.

Whereas the average age in cases of carcinoma of the jejunum was found by Rankin and Mayo [6] to be 47.5 years, this was later revised by Mayo and Nattrour to 51 years. Keyser reported the average age to be 43.9 years. Raiford [7] found 52 as the average age. In four necropsy records of carcinoma of the jejunum from the Cook County Hospital the average age was 47.5 years. The sexes were equally represented.

From a review of the clinical histories in the cases reported, it is apparent that in the majority there were symptoms of acute and chronic intestinal obstruction. Our case differed from these in that the first clinical manifestation was acute perforative peritonitis, which clinically closely resembled that seen in perforation of a peptic ulcer. In an extensive review of the causes of spontaneous pneumoperitoneum by Vaughan and Singer [8] in 1929, two pathologic entities were strongly emphasized, namely perforation of a peptic ulcer and perforation of a gastric carcinoma. Although the lesion in our case was in the jejunum, at the onset it was impossible to differentiate it fluoroscopically from the more frequent perforation of stomach or duodenum. The great rarity of perforation of carcinoma of the jejunum precludes its preoperative diagnosis even in the presence of acute abdominal symptoms if there is no previous history or roentgenologic evidence of a lesion of the small intestine.

The cardinal features in the clinical picture of carcinoma of the small intestine are as a rule those of chronic intestinal obstruction associated with moderate anemia, melena and loss of weight. The absence of these symptoms in our case and the picture of acute perforation of a hollow viscus precluded its preoperative diagnosis.

Whereas in primary carcinoma of the jejunum extensive metastases to the lungs have been recorded by Malerich [9] and to the liver by Milles,[10] in our case they were limited to the radix of the mesentery and the regional lymph nodes.

SUMMARY

A case of primary adenocarcinoma of the jejunum with acute perforative peritonitis was observed in a white man aged 48.

Clinically the picture was that of an acute perforation of a hollow abdominal viscus, as evidenced by sudden abdominal pain, rigidity of the abdomen and the presence of free air beneath the diaphragm.

The condition was clinically indistinguishable from the more common type of perforation, namely perforated peptic ulcer and perforated gastric carcinoma.

In the majority of cases of carcinoma of the jejunum symptoms of intestinal obstruction are associated with melena, moderate anemia and loss of weight. These symptoms were absent in our case.

From a review of the literature it is evident that carcinoma of the jejunum is rare, having an incidence of 0.9 to 0.15 per cent among all the carcinomas of the gastrointestinal tract.

TUMOR OF THE SPINAL CORD COMPLICATING TABES DORSALIS

HAROLD F. BUCHSTEIN, M.D.
Fellow in Neurosurgery, the Mayo Foundation
AND
J. GRAFTON LOVE, M.D.
ROCHESTER, MINN.

When a patient has a chronic syphilitic condition of the spinal cord and a second and unrelated lesion of the spinal cord develops, the latter may escape detection. The case reported here appears to be the first recorded instance of the diagnosis and successful removal of a glioma of the cauda equina from a patient who had been known to have tabes for some years.

REPORT OF CASE

A married man, aged 48, was referred to the Mayo Clinic in January 1938 with a diagnosis of tabes dorsalis. In 1905 he had had a chancre and had received inunctions of mercury. In 1920, when he had complained of headaches and diplopia, a physician had discovered that deep reflexes of the lower extremities were absent and that Argyll Robertson pupils were present. The Wassermann reaction of the blood was positive. Eighteen injections of neoarsphenamine reversed this reaction. Several years later, typical tabetic lancinating and spot pains had appeared in the lower extremities and had continued to occur in spells several times each month until 1937; in that year none had been experienced

Gradual decrease in both libido and potentia had begun in 1930 and both had been absent by 1933. In 1936 the patient had noted absence of the normal sensation of fulness of the bladder and difficulty in emptying it. With time, rectal function had become similarly impaired. In May 1936 spinal puncture had been performed. The cerebrospinal fluid obtained was xanthochromic and contained an excess of protein and 10 cells per cubic millimeter. Intensive therapy with neoarsphenamine, bismuth compounds and tryparsamide was begun. However, the patient's symptoms had progressed, weakness and incoordination of the lower extremities becoming the most distressing symptoms. The patient finally had been reduced to getting about with a cane and had been forced to resign his employment. Spinal puncture again revealed a yellow fluid and led to the patient's being sent to the clinic.

The pupils were small, unequal and irregular. They reacted in accommodation but not to light (Argyll Robertson pupil). Power of the hamstring muscles of both thighs was reduced and that of the muscles of both legs and feet was markedly impaired. Deep reflexes of the upper extremities were normal but those of the lower extremities were absent. Abdominal reflexes could not be obtained. Signs indicative of injury to the pyramidal tract were not elicited. Romberg's test gave a positive result. The anal sphincter was atonic.

Sensibility to painful stimuli was markedly diminished over the whole of both lower extremities and, to a less extent, in a patchy fashion over the trunk. Testicular pressure was not painful. An exact "sensory level" could not be demonstrated. Sensibility to touch and temperature were only slightly impaired. Vibratory sense was well preserved but joint sense was seriously impaired in both feet. Tests of coordination were poorly performed with the lower extremities and the patient exhibited a steppage type of gait.

Routine laboratory tests of blood and urine all gave results within normal limits. Roentgenograms of the thorax and of the entire spinal column disclosed no abnormality aside from a narrow lumbosacral joint space. On spinal puncture, however, fluid could not be obtained at the third lumbar interspace; that is, at the interspace below the third lumbar vertebra. At the fourth lumbar interspace a deeply xanthochromic fluid was obtained, in which a pellicle formed spontaneously. The fluid contained 4,000 mg. of total protein per hundred cubic centimeters and 3 small lymphocytes per cubic millimeter; the result of the Nonne test was strongly positive and the Kolmer-Wassermann and Kline tests gave negative results. The Queckenstedt test (bilateral jugular compression) demonstrated almost complete block in the spinal subarachnoid space above the fourth lumbar interspace. In order to localize the obstructing lesion further, additional spinal punctures were performed at successively higher levels. At the twelfth thoracic interspace, fluid could not be obtained. However, at the tenth thoracic level the spinal fluid was only faintly yellow and the Queckenstedt test gave no evidence of block.

Because it was believed that the obstruction probably was caused by a benign neoplasm involving the spinal cord and that it was not of syphilitic etiology, laminectomy was performed by one of us (J. G. L.) Feb. 7, 1938. When the laminae of the third lumbar vertebra were removed, the underlying dura mater was found not to pulsate. The dura mater was opened, exposing a tumor which appeared to fill the caudal dural sac. The laminectomy was extended in both directions until the entire mass could be seen. It extended from the lower border of the twelfth thoracic vertebra to the fourth lumbar vertebra. It was possible to remove the tumor in one piece after severing its connection with the filum terminale below and the conus medullaris above. It appeared to have taken origin from the tip of the conus and it was necessary to sacrifice the distal segment of the conus in removing the tumor. Once the tumor had been removed the fibers of the cauda equina came into view, as they had been displaced anteriorly. On microscopic study Dr. J. W. Kernohan identified the tumor as an ependymoma.

The patient left the hospital on the seventeenth postoperative day, at which time sensation and power in his lower extremities had improved; catheterization was still necessary. Three months after operation the patient reported that his gait was normal and that his legs were of normal strength. He no longer noted sensory impairment of his feet. It was still necessary at times for him to catheterize himself.

COMMENT

To determine when the tumor first produced symptoms is difficult. Probably the alterations in sexual and sphincteric function which began in 1930 were results of growth of the tumor, although the syphilitic lesion may have played some role in their production. Although pain in the lower part of the back and in the distribution of the sciatic nerves almost always is present in cases of tumor of the cauda equina, and is the initial symptom in 80 per cent of cases,[1] such pain was absent in this case, probably because of the preexisting tabetic lesions of the sensory conducting pathways of the spinal cord. The lancinating and spot pains which the patient had experienced for a number of years were typical of tabes and did not suggest the root pains of a spinal cord tumor. Furthermore, these pains had been absent during the year before the patient came to the clinic.

The physical and neurologic examinations gave rather typical signs of advanced tabes dorsalis except that the muscular weakness of the lower extremities was greater than might be attributed to the hypotonia and ataxia of tabes dorsalis. Muscular weakness per se is rarely a prominent symptom of tabes dorsalis.

From the Section on Neurosurgery, the Mayo Clinic.

1. Kernohan, J. W.; Woltman, H. W., and Adson, A. W.: Gliomas Arising from the Region of the Cauda Equina: Clinical, Surgical and Histologic Considerations, Arch. Neurol. & Psychiat. 29: 287-305 (Feb.) 1933.

The first real suspicion of the presence of a complicating lesion arose when lumbar puncture disclosed complete block of the spinal subarachnoid space and a deeply xanthochromic cerebrospinal fluid. The protein content was unusually high (4,000 mg.). The cell count of the fluid was normal and serologic tests gave negative results.

Such conditions do not occur in uncomplicated tabes dorsalis. Xanthochromic cerebrospinal fluid had been recorded in a variety of syphilitic lesions of the spinal cord, such as acute syphilitic meningitis, thrombosis of the spinal arteries and syphilitic meningomyelitis.[2] However, in none of these is the protein content excessive nor is subarachnoid block present. There is another group of syphilitic lesions of the spinal cord, however, in which the classic Froin syndrome may occur, namely a xanthochromic fluid which contains an excess of globulin and lymphocytes and which clots spontaneously on standing. Such lesions are pachymeningitis hypertrophica, chronic syphilitic leptomeningitis and gumma of the spinal meninges or cord. Recently these have been grouped together as "syphilitic pseudo tumors" by Haguenau and Lichtwitz,[3] who emphasized that pleocytosis of some degree is a constant finding in these cases and that the spinal fluid nearly always gives a positive Wassermann reaction. Thus the cerebrospinal fluid in our case was not typical of any definite syphilitic syndrome but, rather, was typical of a neoplasm of the spinal cord, producing complete obstruction of the spinal subarachnoid space.

Furthermore, our inability to obtain cerebrospinal fluid at the third lumbar interspace suggested that a local rather than a diffuse obstructing lesion was present and prompted the use of multiple punctures [4] by means of which the extent of the lesion was determined. This method not only gave more information than would injection of a radiopaque oil below or above the lesion but it also avoided any possible aggravation of an inflammatory process.

TORSION OF THE GALLBLADDER

WILLIAM H. BERRY, M.D., NEW YORK

Torsion of the gallbladder is such a rare condition that of the few cases reported only four occurred in this country. Shipley,[1] in a thorough search of the literature, was able to find twenty-one cases, most of which were reported in the English and German literature.

Before reporting these cases I shall state briefly the five possible anatomic arrangements and positions of the gallbladder:

1. The gallbladder may be embedded in the liver tissue.

2. It may be closely attached to the under surface of the liver with no intervening layer of connective tissue.

3. The outer end of the fundus may be surrounded by peritoneum and the rest attached to the liver, but not actually touching it, because of an interposed layer of fibrous tissue. This is the normal anatomic arrangement.

4. The gallbladder may be completely surrounded by peritoneum and lie free in the abdomen except for its attachment to the cystic duct. This is not a common occurrence. If it were not for the unfortunate case with which these gallbladders become twisted, this anatomic arrangement would be generally accepted as an ideal one from the point of view of the surgeon. All that is necessary in doing a cholecystectomy on such a gallbladder is to ligate the cystic artery and the cystic duct and remove the organ.

5. The gallbladder may be completely surrounded with peritoneum and attached to the liver by a mesentery.

The cases I am reporting here illustrate the last two groups:

CASE 1.—An unmarried woman aged 54, while riding over an unusually rough road August 31, was suddenly seized with excruciating pain in the upper right quadrant. The pain at first localized in the region of the ninth costal cartilage and later became more or less generalized over the entire right side. The pain was soon followed by nausea and vomiting. These three symptoms, being the only ones she presented, became worse until the time of operation September 1, thirty-six hours after their first appearance. She was seen three hours after the onset by her family physician, who made a diagnosis of indigestion and gave her one-fourth grain (0.016 Gm.) of morphine sulfate with no relief of pain. When I saw her thirty hours later she appeared to be very sick and in acute pain. The temperature was 100 F. by mouth and the pulse rate was 95.

Her past history was entirely negative except for constipation and belching of gas. Physical examination revealed that the patient was poorly nourished with scoliosis, the concavity of which pointed to the right side. This deformity brought the right costal cartilage unusually near the crest of the ilium. There was no jaundice. Examination of the head, neck, eyes, mouth, throat, heart and lungs gave essentially negative results, except for the fact that her respirations were almost entirely thoracic and that the abdomen did not move, even on deep inspiration. The abdomen was not distended and there was no visible peristalsis. Palpation of the abdomen failed to reveal any palpable masses but did reveal a very definite rigidity of the entire right side with a maximum point of tenderness just to the right of the umbilicus. This point later proved to be the location of the gallbladder. A diagnosis of either acute cholecystitis or acute appendicitis was made, and the patient was taken to the hospital for operation. The blood count revealed 20,500 leukocytes with 80 per cent polymorphonuclears. The urine was normal except for a trace of albumin with a few pus cells.

On opening the peritoneal cavity I found no trace of free fluid, which is often present in these cases. The gallbladder was first examined and found to be lying a short distance from the under surface of the liver with the fundus pointing downward and backward. The entire organ was completely surrounded with peritoneum. It was tense and its walls were a reddish brown. It was twisted one and one-half times from left to right and, when untwisted, emptied freely. The cystic duct had a short mesenteric attachment to the liver in which lay the blood vessels. Thus the cystic duct acted as a central point about which the gallbladder could rotate at will. A cholecystectomy was performed by ligating the cystic artery and cystic duct and removing the gallbladder. The appendix was next visualized and its vessels were injected. The lumen contained two fecaliths. An appendectomy was performed and the abdomen closed in layers. Recovery was uneventful except for the fact that a stitch abscess developed on the tenth day.

The pathologic examination revealed the gallbladder 8 by 4.5 cm. in diameter, reddish brown and filled with thick, dark brown fluid. The mucous membrane was swollen and congested. There were no calculi. The wall of the gallbladder contained several small hemorrhagic areas.

CASE 2.—An Italian woman, aged 23, married, came to St. Luke's dispensary with a history of attacks of pain in the epigastrium. The pain was colicky and radiated through to the right shoulder. This was followed by nausea and vomiting. She had had several such attacks in the last four years. Her past history was otherwise irrelevant. A roentgenogram showed a nonfunctioning gallbladder. She was admitted to the surgical service and a cholecystectomy was done. The gallbladder was completely surrounded with peritoneum and attached to the under surface of the liver by a mesentery. It contained several small stones. A cholecystectomy was done by simply clamping and ligating the mesentery and likewise the cystic duct.

This case represents the fifth anatomic group.

From a clinical point of view there are two types of torsion of the gallbladder, namely complete and incomplete. In complete torsion there is strangulation of the blood supply and gangrene of the gallbladder. The symptoms are acute, beginning with dramatic suddenness. In incomplete torsion there is interference with drainage of the gallbladder. The symptoms are insidious in onset and resemble those of chronic cholecystitis.

It was interesting to note that nineteen of the twenty-one cases reported occurred in women, all but two over 50 years of age and the majority over 70. Gallstones were present in only six instances. The direction of the volvulus is not a matter of significance, since seven were clockwise, five were

counterclockwise and the direction of the rest was not mentioned. Three patients died; a fourth case was discovered at autopsy. It was discovered in one case that the common duct was evidently drawn up by the twisting of the cystic duct and ligated. This patient became deeply jaundiced and died twelve days later. Only one case was diagnosed properly; the other cases were diagnosed practically everything concerned with the abdomen from indigestion, as in this case, to twisted ovarian cyst, cholecystitis being the most frequent diagnosis.

In the majority of cases the onset was very sudden and in only one case was there a previous history of discomfort in the upper quadrant of the abdomen. The clinical picture is so definite that, according to Lett,[2] pain in the upper right quadrant of the abdomen beginning with dramatic suddenness, followed by nausea and vomiting, with very slight elevation of temperature, a moderate increase in the pulse rate, occurring with or without a palpable mass in a woman over 65 with no previous history of gallstones, should always make one suspicious of torsion of the gallbladder. However, the condition is so very uncommon that its likelihood of being present is usually not considered.

Special Articles

THE PHARMACOPEIA AND THE PHYSICIAN

IMMUNOLOGIC METHODS IN PEDIATRICS

ARCHIBALD L. HOYNE, M.D.
CHICAGO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

Susceptibility of the individual is a necessary factor when considering the application of an immunizing agent. In many instances age exerts a controlling influence on susceptibility. It is well known that smallpox, erysipelas, whooping cough and chickenpox may occur in very early infancy. Any of these diseases may be encountered during the first few weeks of life; smallpox and erysipelas may develop soon after birth. Various forms of meningitis also occur very early. Diphtheria and scarlet fever are not common before 1 year of age and are rare under 6 months; the same holds true for poliomyelitis. Measles is very infrequent prior to the first half year of life.

PROCEDURES FOR ACTIVE IMMUNITY AGAINST SOME OF THE MORE COMMON INFECTIOUS DISEASES

In view of the foregoing facts, vaccination against smallpox should be the first protective measure to be adopted in the life of the child to afford artificial immunity. If the infant is in good health and without any cutaneous disorder such as eczema, from the third to the fourth month offers a good time for this procedure. In the presence of known exposure to smallpox there is no contraindication to vaccination. If possible it is preferable to choose cool weather for the inoculation, when there is less likelihood of secondary infection. The multiple pressure method is superior to all others. Failure to secure a successful vaccination in an unvaccinated individual should never be construed as an indication of immunity. This statement is based on the assumption that the patient has not had smallpox.

Next in order, immunization against whooping cough may be undertaken. For this purpose Sauer's vaccine is injected subcutaneously. It is given at weekly intervals, two injections each time in doses of 1 cc., 1.5 cc. and 1.5 cc., making a total of 8 cc. or about 80 billion bacteria. It requires about four months for immunity to develop. Therefore if inoculations are made at 3 months of age the baby cannot be assumed to have protection from whooping cough before it is 7 months old.

Diphtheria immunization can be instituted at 9 months. This is best accomplished by the subcutaneous injection of three doses of toxoid or two doses of alum precipitated toxoid. In either instance the dose is 1 cc. with an interval of from three to four weeks between injections. In many cities of the United States only one dose of alum precipitated toxoid is employed. It is presumed that the antigenic response is sustained over a more prolonged period with the latter preparation than when plain toxoid is used. However, although immunity with alum precipitated toxoid may be established within two months, it does not last for more than two years in about 50 per cent of cases. It is well to perform a Schick test six months after administration of toxoid to determine its success.

Ramon, who introduced toxoid for diphtheria immunization, now strongly recommends that tetanus toxoid be administered in combination with the diphtheria toxoid. His method consists of injecting subcutaneously 2 cc. of the combined toxoids on three occasions at intervals of three weeks. This plan seems very desirable and will undoubtedly be given wider acceptance in the future.

The Dick method for active immunization against scarlet fever has not received the general approval of pediatricians. Fear of severe reactions, the multiplicity (five) of injections and the belief that immunity to hemolytic streptococcus infections is not assured deter many from adopting the method. Nevertheless in hospitals and institutions where large numbers of children are housed the procedure is of undoubted value. Robinson [1] has reported favorable results with intracutaneous injections of scarlet fever toxin. In this manner less toxin is used, fewer (three) injections are made and reactions are avoided. Lately Earle [2] of Desplaines, Ill., has used this plan successfully. Previously others had reported the intradermal method for active immunization against anthrax, typhoid and diphtheria.

Immune globulin (placental extract) may be injected intramuscularly with the object either of preventing or of modifying measles. If the intention is to prevent measles, 2 cc. should be injected within forty-eight hours of exposure and the same size dose repeated about five days later. For modification 2 cc. of the immune globulin is injected usually from five to seven days after exposure. It must be remembered that the method for prevention constitutes only a temporary immunity. On the other hand, modification of the disease results in the same degree of immunity as occurs after an unmodified attack of measles. Modified measles, however, can be transmitted to those who are susceptible, and these may suffer from severe attacks. For this reason the method for modification is not suitable, as a rule, in hospitals or institutions where the necessary aim is generally prevention.

Active immunization against typhoid is a thoroughly reliable procedure. Typhoid vaccine usually contains

2. Deceased.

about one billion bacillus typhosus organisms per cubic centimeter. Combined with this about 750 thousand each of paratyphosus A and B are frequently used. The vaccine is administered subcutaneously in three doses of 1 cc. each at seven to ten day intervals. The point of injection is usually over the deltoid muscle. Protection generally lasts for about three years.

METHODS FOR PASSIVE IMMUNITY AND TREATMENT

Animal and human antiserums are valuable therapeutic aids in certain acute infectious diseases. Their efficiency has been firmly established for both prophylactic purposes and treatment of acute conditions.

Diphtheria antitoxin is the best example of a thoroughly efficient animal serum for the treatment of disease. Antitoxins for tetanus, scarlet fever, meningococcic infections, staphylococcic infections, gas bacillus and erysipelas are among the better known. All of these are produced in the horse. Tetanus antitoxin is sometimes developed in the cow as well. Bovine tetanus antitoxin may be used for man when known sensitivity to horse serum exists. Antipneumococcus horse serum, which was first available for pneumonia of types I and II, is now produced also in the rabbit. The field of usefulness for antipneumococcic serum is being rapidly expanded by the production of antiserums for a number of the other types, including III, IV, V, VI, VII, VIII and XIV.

PROPHYLACTIC DOSAGE

Estimation of the proper dose for any one of the antiserums is sometimes a difficult problem. There is no standard rule or method which is always satisfactory. For diphtheria prophylaxis, when immediate protection is desired for a susceptible contact, it is a common practice to administer 1,000 units of diphtheria antitoxin. This quantity is injected intramuscularly. Since the protection afforded is a passive immunity it is not enduring and usually does not last for more than from ten days to three weeks, the antitoxin being rapidly eliminated. For passive immunity to tetanus the dose is generally 1,500 units, though sometimes because of the nature of an injury or on account of delayed administration double that quantity is injected and occasionally for special reasons the dose should be repeated in five days. Needless to state, the antiserum should be given at the earliest possible moment.

DOSAGE OF ANTISERUMS FOR ACUTE STAGE

I have referred to the fact that there is no satisfactory method for determining accurately the dose of an antiserum which is applicable to all patients. Nevertheless a mathematical means for gaging the dose of diphtheria antitoxin was offered many years ago. It was stated that 100 units per kilogram of body weight was sufficient for a mild or average attack of diphtheria and that 500 units per kilogram sufficed for severe diphtheria. In practice this mathematical method is not satisfactory. It seems much more important to base the dose on the site of infection and the duration of the disease. In postnasal or nasopharyngeal diphtheria the rate of absorption of toxin is much more rapid than when the diphtheria membrane is confined to the tonsils. Consequently the dose of antitoxin should be greater in the former condition. Likewise the longer the patient has been ill without antitoxin administration, the greater is the quantity of toxin produced and therefore the larger is the amount of antitoxin required. However, since toxin combines with the body tissues and is not then readily vulnerable by the antitoxin, it is principally the free toxin which can be neutralized or rendered inert by antitoxin. This makes the necessity for early administration of antitoxin apparent and explains why diphtheria antitoxin is not of value in the treatment of postdiphtheritic paralysis.

One's own experience must serve in a large measure as a guide in deciding how much antiserum shall be used for any given patient. In an experience of more than twenty-five years in contagious disease hospitals I have found that diphtheria antitoxin in excess of 60,000 units is seldom if ever beneficial. In most instances our total dose is not more than 40,000 units. Having decided on the maximum amount of antitoxin that seems necessary it is best for one to give the total quantity at once and not in divided doses. If it is later believed that an error in judgment occurred regarding the size of the dose, an additional amount should be injected. The administration of diphtheria antitoxin does not constitute the sum total of all treatment. It is the primary and most important part of treatment except in certain types of laryngeal or laryngotracheal diphtheria in which surgical intervention is even of greater necessity than antitoxin. A discussion of intravenous dextrose as an adjuvant in the treatment of diphtheria is not within the province of this article.

Tetanus antitoxin presents even more difficult problems for solution in respect to dosage than does diphtheria antitoxin. Again experience must be the judge. Lately the tendency to give extremely massive doses of tetanus antitoxins has not been so apparent in some sections of the United States. Increasing dependence seems to be placed on sedation, some believing from 60,000 to 100,000 units of tetanus antitoxin sufficient for any tetanus patient whose recovery is possible.

What has been said with regard to diphtheria and tetanus antitoxin dosage also applies to the use of scarlet fever antitoxin and any of the other immune serums whether they are antitoxic or antibacterial products. Early administration is of great importance. The age of the patient is not as essential a factor in deciding on dosage as virulence of the organisms, susceptibility of the patient, duration of the disease and in some instances the site of the infection. Nothing, however, is so helpful as one's own experience.

ROUTES FOR INJECTION

Most antiserums have been given by one of three routes: (1) subcutaneous, (2) intramuscular or (3) intravenous. Originally the subcutaneous method of injecting antiserums was the most common. Today it is the least used. The intramuscular route is the one most often employed. Absorption is much more rapid and there is less pain when the antiserums are properly administered; it is also a reasonably safe procedure which can be adopted in the home as well as in the hospital.

During recent years particularly, intravenous therapy has been broadly extended. This route was strongly advocated by some for the administration of diphtheria antitoxin more than twenty years ago. The method is not recommended for patients confined in the home. From time to time it is selected for hospitalized diphtheria patients. It is doubtful whether the administration of diphtheria antitoxin intravenously will save a patient who would not recover by means of intramuscular treatment. On the other hand there is an increased tendency, as previously mentioned, to use the intravenous route for immune serums.

In the contagious disease hospitals of Chicago all antimeningococcus serum and meningococcus antitoxin are given by the intravenous route. Nothing is introduced intraspinally when treating patients with meningococcic infections whether there is evidence of meningitis or not. This change in method of treatment was made by us in 1934, before the introduction of sulfanilamide, and has produced excellent results. The belief that tetanus antitoxin should be given intraspinally is no longer universally accepted. It is my opinion that the treatment of tetanus without intraspinal therapy is advisable. In any form of blood stream infection, intravenous administration of an antiserum seems logical. In this connection outstanding examples are septicemias due to the meningococcus, streptococcus and staphylococcus.

In the past, antiserums have been administered in practically every conceivable manner. In addition to those routes mentioned are the intracisternal, intraperitoneal, intrapleural and also oral and rectal. Today the intramuscular and intravenous routes are the methods of choice.

Regardless of the route chosen, serum should not be injected when cold. Under such a condition it is likely to cause severe pain if injected in the muscle and will be absorbed slowly. If cold antiserum is given intrathecally or intravenously, it may cause serious shock. The serum should be at body temperature before administration regardless of the route chosen. But a temperature much above 98 F. may lessen or destroy the potency of serum and even cause coagulation.

INTRAVENOUS ADMINISTRATION OF SERUMS

Any animal antiserum when given intravenously is best diluted in physiologic solution of sodium chloride or in from 5 to 10 per cent dextrose in saline solution. The diluent should be of at least equal volume to the serum; it may be more than double the volume. To the mixture we add from 5 to 15 minims (0.3 to 1 cc.) of solution of epinephrine hydrochloride (1:1,000) depending on the age of the patient. The drip method should be selected and the flow at body temperature ought not exceed from 10 to 15 drops a minute at first. Later if the patient shows no unfavorable symptoms the rate of flow can be increased often to 60 drops a minute. With this method I have given as much as 1,200 cc. of horse serum (meningococcus antitoxin) to a patient within four days' time without any disturbing symptoms being noted.

SERUM SICKNESS

Fear of serum reactions has existed in the minds of physicians since the early adoption of biologic products for therapeutic purposes. While it is well known that serum reactions have been of common occurrence in connection with the administration of animal serums, the possibility of fatal consequences often has been magnified greatly during past years. Among 20,000 diphtheria patients treated in the Municipal Contagious Disease Hospital, Chicago, from 1917 to 1938, no anaphylactic death has occurred. Nor has it ever been customary to make routine sensitivity tests in that institution.

With the improved methods for concentration and refinement of animal antiserums which are in use today there is less reason than ever before to anticipate a high frequency of protein shock as a result of serum administration. Nevertheless it must be realized that serum reactions do occur and proper means should be adopted in an endeavor to prevent or minimize them.

If a patient is known to be sensitive to horse serum it may be possible to avoid the use of serum of that animal. This can be done in the case of tetanus by giving bovine tetanus antitoxin. If horse serum must be used for an asthmatic patient or some one who is known to have been treated with a horse serum on some previous occasion, it is well to make a sensitivity test and, if positive, to attempt desensitization by the usual graduated injections of small amounts of the serum. Although this is a worthy procedure, its actual value sometimes seems doubtful.

The usual form of serum sickness manifests itself in from eight days to two weeks following injection. If the serum was given intravenously the reaction generally occurs earlier, often in from six to ten days. The symptoms presented include some or all of the following: elevation of temperature, urticarial eruption, painful joints and lymphadenitis. It is worthy of note that serum sickness of this type when developing in patients with meningococcic meningitis may be accompanied by an increase in cell count and spinal fluid pressure.

Treatment consists of solution of epinephrine hydrochloride (1:1,000) from 0.3 to 0.5 cc. subcutaneously, intramuscularly or intravenously, depending on the degree of reaction. Free catharsis and local application of calamine lotion to relieve itching is helpful. In my experience the administration of calcium gluconate intravenously has not been of marked value. Nevertheless it is sometimes deserving of trial.

Accelerated or immediate reactions may develop in persons who have been treated previously with horse serum. Such reactions may occur within a few hours following serum administration or during the progress of intravenous serum injection. Reactions of this kind are not necessarily more severe than those previously described as the usual form.

ANAPHYLACTIC SHOCK

The most severe of all serum reactions may develop almost at the instant the serum is injected or follow within a period of about one hour. The severity of the reaction does not always seem to depend either on the amount of serum given or on the route selected. Sometimes there is a convulsion, the pulse rate becomes very rapid and is thready in character, cyanosis may develop, respirations are accelerated and shallow, profuse sweating occurs and death takes place. Pulmonary edema is usually present under such circumstances. Should acute anaphylactic shock occur, solutions of epinephrine hydrochloride (1:1,000) from 0.5 to 1 cc. should be administered at once. If the serum was administered in an extremity, a tourniquet should be applied proximally to the site of injection.

ARTHUS PHENOMENON

The Arthus phenomenon is a local tissue reaction and is occasionally seen when a second injection of animal serum is made near the site of a former injection. It is never likely to occur if the second injection is made within five days' time. It is characterized by swelling and marked induration, which may involve both the subcutaneous and the muscular tissues. As a rule the reaction does not develop rapidly but may result in a marked sloughing of tissue. There may be considerable pain in the part involved, which generally is better relieved by cold compresses than by hot applications. To avoid the possibilities of an Arthus phenomenon it is well never to make a second subcutaneous or intramuscular injection of serum near a prior one.

HUMAN IMMUNE SERUM

Sometimes it is asserted that human convalescent serum should be of particular value in the prevention or treatment of virus diseases. Practical experience does not indicate that such a contention is always true. Whereas it is a fact that the serum of convalescent patients is of great value in the prevention of measles and to some extent as a prophylactic for chickenpox when given early enough, it is generally believed that convalescent poliomyelitis serum is worthless for preventive purposes; nor is there sufficient evidence to uphold an opinion that human convalescent serum is of value for the treatment of any of these diseases. Convalescent serum has also been used for the prevention of mumps and whooping cough and for the treatment of a number of nonviral diseases including scarlet fever, meningococcic meningitis and erysipelas. The folly of administering convalescent serum for the last named disease should be apparent when one considers that the average erysipelas patient acquires practically no immunity from an attack of the disease. Consequently there is no basis for anticipating that the blood or serum of a convalescent erysipelas patient will contain sufficient antibodies to be of therapeutic value.

MEASLES CONVALESCENT SERUM

Human convalescent measles serum is of undoubted value for prevention when administered within three days of exposure. The dose, injected in the outer muscles of the thigh, varies from 5 to 10 cc. according to the patient's age. Protection is only temporary, usually from ten days to three weeks. When convalescent measles serum is administered more than three days after the exposure of the susceptible person, it is likely to modify the disease even if it does not prevent it.

Normal adult serum or whole blood is also used for passive immunization against measles. In either case the quantity injected should be greater than if convalescent serum were being used. For normal serum the dose is generally from 10 to 20 cc., while for whole blood as much as 30 cc. is required.

Human convalescent serum for chickenpox, mumps and whooping cough has been employed in a manner similar to the measles serum but not with the same degree of success. Convalescent scarlet fever serum is of value as a prophylactic.

Of all human immune serums to be used, convalescent scarlet fever serum seems to be by far the most efficient. Nevertheless it has been claimed that human convalescent scarlet fever serum is only one thirtieth as potent as scarlet fever antitoxin. The latter conclusion seems doubtful from observations made on the treatment of several thousand cases of scarlet fever with human convalescent serum. Possibly human immune scarlet fever serum possesses some therapeutic properties which cannot be measured by ordinary laboratory methods.

The advantage of immune human antiserums of known efficiency over animal serums is the absence of serum reactions. For this reason repeated doses regardless of time intervals may be injected without fear of serum sickness. Moreover, serum may be given in large quantities, if need be, by the intravenous route without unpleasant effects and without the necessity of dilution. When administering human antiserums intravenously it is needless to say that no typing or matching of blood is required. For a number of years practically all human convalescent scarlet fever serum used in the contagious disease hospitals in Chicago has been injected by the intravenous route. The dosage generally varies from 20 to 100 cc., depending on the severity of the case.

Immunotransfusion in the treatment of acute infectious diseases is sometimes adopted as a last resort when the prognosis seems to be particularly desperate. Selection of the donor involves the necessary typing of blood, and the success of the undertaking is influenced by the antibody content of the source of the blood. The transfusion in itself, however, may be of great benefit regardless of any immunizing substances transferred by the operation.

LYOPHILE

Lyophile, dried human blood serum, offers great possibilities. It is prepared by freezing at low temperatures and rapid dehydration under high vacuum. Lyophile can be preserved for long periods in sealed ampules and antibody properties retained. For use it is merely dissolved in sterile distilled water. Convalescent serums have been subjected to this process and the lyophile injected for therapeutic purposes. Bond and Wright at the University of Pennsylvania have reported on the intravenous injection of lyophile following shock or hemorrhage.

Eventually sulfanilamide may displace, to a considerable extent, some of the biologic preparations now in common use. This new drug is particularly effective in erysipelas and streptococcic meningitis. It is also of undoubted value in meningococcic meningitis. But its value in scarlet fever seems very questionable on the basis of personal observations.

CONFERENCES ON THERAPY

TREATMENT OF INFECTIONS OF THE GENITO-URINARY TRACT

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. MCKEEN CATTELL: Our subject this morning, "The Treatment of Infections of the Genito-Urinary Tract," is one in which there has been a considerable advance in the past few years, an advance which has included the introduction of a number of new drugs. Dr. Modell will open the discussion with a presentation of some of the broader principles of treatment and a consideration of the pharmacology of some of the drugs employed.

DR. WALTER MODELL: There are four general problems in the treatment of urinary infections: (1) the regulation of urinary volume, (2) the regulation of the urinary p_H, (3) the effect of antiseptics on the human host and (4) the effect of the antiseptics on bacteria.

Urinary volume may be shifted in either direction, toward an increase or a decrease. The volume of urine may be increased in an attempt either to flush out the urinary tract or to dilute the irritants which are found in infected urine, or it may be decreased to obtain a more concentrated solution of an antiseptic which is being used. Either can be achieved by regulating the water intake. To increase the volume, as much as 5 or 6 liters of water a day may be given; to decrease it, fluid may be limited to 1 or 1.5 liters a day.

The regulation of the p_H of urine is important. A change of the urinary p_H may itself exert antiseptic actions. Furthermore, some of the antiseptic agents are either most effective or effective only within certain p_H ranges. In an extensive series of observations the p_H of normal urine was found to vary from about 4.8 to 7.5, with the mean at about 6. The excretion of acid urine is an expression of mechanisms in the body which maintain the constancy of p_H in the blood. Because of the efficiency of these mechanisms it is possible to achieve marked changes in urinary p_H without affecting the p_H of the blood. The important buffers in the urine are the *mono*-sodium *di*-hydrogen phosphate and the *di*-sodium *mono*-hydrogen phosphate. In the plasma the ratio of acid to basic phosphate is about four to one in favor of the basic phosphate. In the excretion of these substances by the kidneys most of the basic phosphate is reabsorbed in the tubules and the acid phosphate is excreted so that in the urine the ratio is reversed to about nine to one in favor of the acid phosphate. However, if the diet is alkali forming, more of the basic phosphate is excreted and the urine becomes alkaline.

The urinary p_H can be changed by dietary measures by interference with the carbohydrate and fat metabolism and by the use of drugs. In a general way a vegetable diet or alkaline-ash diet results in the development of alkaline urine, whereas a high protein diet or acid-ash diet produces an acid urine. There are some vegetables which contain benzoates which give rise to the elimination of hippuric acid, which in turn tends to acidify the urine. It is rarely possible by dietary measures alone to produce the extremes of acidity and alkalinity which are therapeutically useful. The ketogenic diet will be discussed later.

Alkalizers are sodium and potassium bicarbonates, sodium and potassium citrates and sodium and potassium acetates.

Acidifiers are solution of hydrochloric acid, solution of phosphoric acid, solution of nitrohydrochloric acid, sodium acid phosphate, ammonium chloride and ammonium acid phosphate.

Drugs afford the simplest way of changing the urinary p_H. In order to make the urine alkaline there are a number of alkalis other than those listed which are effective. Sodium or potassium bicarbonate may be given, but the citrates and the acetates are used more frequently because they have little effect on gastric acidity. In the body the latter are oxidized and excreted mainly as carbonate, so that the urine becomes alkaline.

There are various substances which make the urine acid. One can use acids: hydrochloric acid, phosphoric acid or nitrohydrochloric acid. One of the most commonly used drugs for acidifying is sodium acid phosphate. I think it deserves special mention. Sodium acid phosphate is a buffer. It acts as such when eliminated in the urine and therefore is not a very reliable acidifying agent. It has been reported to make some urines more alkaline. Sodium acid phosphate was used most enthusiastically when urinary acidity was determined by titration against alkali. However, when changes in urinary acidity were studied in terms of hydrogen ion concentration it was found that the sodium acid phosphate was not as effective as formerly thought. It is also important that sodium acid phosphate is poorly absorbed, and if large doses are taken it acts as a cathartic.

The ammonium salts are much more reliable, and it is easy to understand why. In ammonium chloride, for example, the ammonium fraction is split off and converted into urea, leaving free hydrochloric acid; similarly with other ammonium salts, free acid radicals are left after the conversion of the ammonium to urea. It is therefore possible to effect marked changes in urinary p_H, and if large doses are used it is also possible to produce a true acidosis. This is an especially important consideration in the face of renal insufficiency. If the usual doses of ammonium chloride do not produce acid urine it is wise to examine the carbon dioxide combining power of the blood to determine whether acid is accumulating in the blood. The impaired kidney may not be able to excrete acid rapidly enough and acidosis may develop without appreciable change in the p_H of the urine.

I think it is well to mention in discussing urinary acidity that it has been stated that therapeutic doses of the acidifying agents cannot shift the urinary p_H beyond the extreme acid limits of normal urine; that is, beyond 4.7 or 4.8.

The use of alternate acidification and alkalization in an attempt to eliminate infections is, I think, outmoded. It has been shown that certain organisms, such as B. coli and some of the streptococci and staphylococci, remain viable in mediums the p_H of which is beyond the limit to which one can shift the urine either in the alkaline or in the acid direction by the use of drugs.

URINARY ANTISEPTICS

A partial list of some of the urinary antiseptics which have been used includes oil of santal, hexylresorcinol,[1] pyridium,[1] serenium,[1] picochrome (benzochrome),[1] methylene blue, mercurochrome, acriflavine, potassium permanganate, strong protein silver, methenamine, sulfanilamide, the ketogenic diet (beta-hydroxybutyric acid) and mandelic acid (sodium and ammonium mandelate). Antiseptics come and go, and the only ones who remain faithful to their memories are their manufacturers.

Up until very recently one of the most common drugs taken by mouth was methenamine. In an acid medium methenamine breaks up and liberates free formaldehyde. A urinary p_H of 5.5 or less is required for this effect. It has been said by some that 0.5 per cent of methenamine is not effective against most organisms and that this concentration is much too irritant to the mucosa of the urinary tract to be used. However, there are many clinicians who have found methenamine an effective agent in the treatment of infections, perhaps the most reliable until recent years.

I think the most important thing about the dyes used in the treatment of urinary infections is that experimentation with some of them aided in the discovery of neoprontosil and sulfanilamide.

We have discussed sulfanilamide here before, but there are several things I want to emphasize:

1. Sulfanilamide not only is excreted in the urine but it also permeates all the tissues of the body, so that it has the advantage of affecting organs associated with the urinary tract, such as the prostate and seminal vesicles, which are not drained or flushed by urine.

2. As sulfanilamide is quantitatively excreted in the urine, it is possible by controlling the urinary volume and regulating the dosage to achieve desired concentra-

1. These do not stand accepted by the Council on Pharmacy and Chemistry.

tions of sulfanilamide. The minimal effective concentration in the urine is said to be between 100 and 200 mg. per hundred cubic centimeters, or between 0.1 and 0.2 per cent of sulfanilamide.

Sulfanilamide is said to be most effective in an alkaline medium, but alkaline urine is not essential since it is quite effective in an acid urine as well.

The ketogenic diet, which consists primarily of eggs and heavy cream, has been shown to be an effective means of treating urinary infections. In the ketogenic diet because of the limited amount of carbohydrate the high fat content is not completely metabolized and large amounts of the ketone bodies are eliminated in the urine, the urine becoming highly acid. The chief disadvantage is that it is very unpleasant and that the amounts of eggs and cream used run up the cost of therapy considerably. It has been demonstrated that the effective agent in the ketogenic diet is beta-hydroxybutyric acid, which is eliminated in the urine. Unfortunately beta-hydroxybutyric acid cannot be used in the normal as a therapeutic agent because it is completely metabolized except in the presence of ketosis. It may, however, be used to fortify the ketogenic diet itself or it can be introduced directly into the urinary tract. It was the bactericidal action of beta-hydroxybutyric acid which led to the discovery of mandelic acid.

Rosenheim, investigating a number of hydroxy acids, found that mandelic acid, which is eliminated quantitatively in the urine, is effective against a number of bacteria in vivo as well as in vitro. Mandelic acid is effective only when the p_H is 5.5 or less. The minimal concentration of mandelic acid necessary in the urine is about 0.5 per cent, although if the p_H of the urine is considerably below 5.5 a less concentrated urine may be effective. Mandelic acid is fairly rapidly absorbed, and twenty-four hours after a single dose almost all of it is eliminated in the urine. Mandelic acid often causes gastric disturbances, and it has also been reported that it causes transient renal function changes. In order to avoid the gastric disturbances, the sodium salts and the ammonium salts of mandelic acid have been used. It is well to mention that ammonium mandelate has the additional advantage of being an acidifying agent. However, even with ammonium mandelate it is generally necessary in order to get urine sufficiently acid to use some acidifying salt, such as ammonium chloride and dietary measures. The water intake is usually limited.

The drugs I have considered are those which, when taken by mouth, are eliminated as effective agents in the urinary tract. These act presumably from the renal pelvis down. There are various substances, such as acriflavine and other acridine dyes, the silver proteinates and potassium permanganate, which are injected directly into the urethra and sometimes into the bladder. There are advantages in each method of treatment. However, a urinary antiseptic which can be taken orally generally acts for a considerably longer period of time than those introduced directly into the urethra and also acts over a greater part of the urinary tract.

The broad pharmacologic aspects which have been considered are not the only factors which determine the therapeutic regimen in urinary infections. There are other clinical features in patients which influence the choice of drug and details of therapy. These will now be discussed.

SOME PRACTICAL CONSIDERATIONS OF TREATMENT

DR. ALEXANDER R. STEVENS: The practical application of these drugs I think should be preceded by a few observations on the different kinds of infections that occur in the urinary tract. Otherwise one proceeds rather blindly. As you know, urinary infections may be put into two groups with respect to the initial site. They may begin in the excretory part of the urinary tract and therefore show pus and bacteria in the urine very early, or they may begin in the deeper structures, notably the parenchyma of the kidney and prostate, and may not show any pus or bacteria in the urine. One has two very different problems in these two types of cases. In individuals with pus and bacteria in the urine one might expect benefit from the use of a drug which is excreted in the urine as an antiseptic, a bactericide or even only a bacteriostatic agent, whereas one would expect, a priori, little or no help at all in treating, for instance, a cortical infection of the kidney or prostatitis. It is only in comparatively recent times that we have had an antiseptic drug which is present actively in the blood and the tissues as well as the urine. That widespread activity opens up the field of the treatment of deep-seated infections.

As for urinary tract infections that occur with pus and bacteria in the urine, there again one must consider two groups: one without any foreign body or obstruction in the urinary tract, and the other with foreign body or an obstruction. Those patients without any calculus, which is the foreign body I refer to especially, or without any obstruction in the urinary tract (whether it is in the ureter, bladder or urethra, the problem is one) may acquire acute infection and recover spontaneously without any specific treatment. Indeed, one meets with many such acute infections, which clear up entirely without any recurrences, with merely hygienic care and rest in bed, whereas the patients who have foreign bodies (such as drainage tubes and calculi) or obstructions are rarely permanently relieved of urinary infections without the proper care of those foreign bodies and obstructions. Occasionally one can sterilize the urine behind the obstruction, but usually not until that obstruction is taken care of. The tendency these days I think is to give one of these more potent, more recent, remedies and forget the underlying trouble which not only makes possible and probable a quick recurrence of infection but also may itself do considerable harm to the upper urinary tract.

Most of the antiseptics that have been listed here I think are enumerated largely for historical perspective. I myself have tried practically everything on that list and would be perfectly willing in practice to eliminate everything down to methenamine (urotropin). Many of the other drugs are notable largely for their colors, both before administration and as excreted in the urine. If a patient wants his linen stained any particular shade, one can pick a drug to accommodate him but that is about all the satisfaction he gets. Many articles have been written on all of these so-called antiseptics, listing records of hundreds of patients who have profited by them, but I think you will find that most urologists today are very skeptical of the whole batch.

Methenamine, as you have just heard, is active chiefly because in an acid urine it breaks down, producing formaldehyde, but it is active only in urine and not in the tissues. It is excreted from the kidney as such

and breaks down after excretion, so that one may expect help only in the type of infection that is associated with the excretory urinary passages. This therapy is comparable to continuous irrigation over the mucous membrane with a very mild antiseptic solution. It does not get down in the depths of the tissues. If you are dealing with a deep-seated infection of the kidney, the pelvis, the bladder or the prostate, little or no therapeutic aid should be expected from methenamine. Its great value I think is as a prophylactic. I have often asked patients whom I was going to treat instrumentally to start taking methenamine twenty-four hours before the treatment and keep it up for twenty-four hours afterward and then quit, merely with the idea that we might prevent multiplication of any bacteria introduced by the passage of urethral instruments.

The ketogenic diet I will speak of very briefly. I think Dr. Modell was very mild in his description of the patient's attitude toward that diet. I have had individuals who could stick it out for a week, and that is about as far as most people want to go. One patient after a week of it would start vomiting when she heard the maid coming down the corridor with her meal tray. The food did not even get into the patient's room. The very thought of all that fat, the olive oil, the butter and the cream started things going. When the ketogenic diet could be replaced by mandelic acid therapy with apparently equal benefit to the patient, there was certainly a tremendous advance.

Mandelic acid is employed very widely. It operates, as you have heard, only in an acid urine. If given in the form of the ammonium salt, it tends to make the urine acid. If necessary to secure greater acidity, one of various drugs may be added, usually ammonium chloride or nitrate. It is necessary to have at least a half of 1 per cent mandelic acid in the urine to be most effective. Some authors suggest twice that much. As you have just heard, the more acid the urine, the more effective the mandelic acid, so that with a very acid urine a lower strength of mandelic acid may suffice. It is usually not given in large enough quantities. It is wise to administer about 12 Gm. in a twenty-four hour period in order to secure sufficient concentration in the urine. Mandelic acid is effective with most organisms which occur in the urine but remember that this therapy is satisfactory only when the p_H of the urine is 5.5 or lower. With certain bacteria, notably the proteus, one rarely can secure such a reaction. Hence in these instances mandelic acid is useless.

Finally the great concentration these days is on sulfanilamide, which has quite revolutionized the treatment of infections in urology. Here is a drug that is potent in dealing with nearly all bacteria, whether found in an acid or an alkaline urine. Those who have done the most work find one or two organisms that are not much influenced by sulfanilamide, but it does dispose of most of the organisms commonly found in urine (cocci and bacilli) excepting the tubercle bacillus. I do not think anybody has claimed anything for that. As sulfanilamide is somewhat more effective in alkaline urine than in acid urine I make a practice, in common with many others, of giving an alkali with the sulfanilamide. There is the great advantage too that it may be administered under the skin or intramuscularly and also intravenously, but the latter route is not very often necessary.

The dosage is usually up to from 5 to 6 Gm. in a twenty-four hour period. The rule that some have advised, which I think is a very good one, is 1 gram for each 20 pounds of body weight, with a maximum, however, of perhaps 6 Gm.; but in some instances patients have tolerated well as much as from 10 to 15 Gm. a day.

There are certain toxic possibilities associated with sulfanilamide that we do not have with most of the other urinary antiseptics. Hence I think one should be cautious in giving sulfanilamide to patients who are not confined to bed and not under constant observation.

There is one drug which is not on the list presented for consideration, which I think you ought to know about, and that is arsphenamine or neoarsphenamine, which is very potent in some instances of coccic infection. Until all this furor over the two new drugs, it was one of the outstanding marvels in urology that in some cases of a pure staphylococcic infection of the urinary tract, which is not very common and which often resists all other forms of treatment, the infections react favorably and quickly to that drug given intravenously.

SPECIAL CONSIDERATIONS RELATING TO TREATMENT DURING PREGNANCY

DR. HERBERT F. TRAUT: I am very glad that Dr. Stevens pointed out the importance of obstructions in connection with urinary tract infections. In pregnancy we have to deal with a physiologic obstruction. The hormones of pregnancy which relax the smooth muscles of the uterus and thus make the continuation of pregnancy possible have a similar effect on the urinary tract. They produce an atony of the ureter, so that its normal peristaltic activities are suppressed and sometimes obliterated. In addition, as pregnancy progresses there is enlargement of the uterus, when the woman is in the upright position the inlet of the pelvis is blocked, and the ureters are occluded more or less completely. The result is urinary stasis, dilatation of the tract and the formation of what has come to be known as the physiologic hydro-ureter of pregnancy.

Unfortunately some women who become pregnant have had pyelitis previously without complete eradication of the infection. In these women who may have chronic pyelitis the physiologic obstruction provides an opportunity for exacerbation. They may, however, have the primary attack during pregnancy. The factors important in the development of the primary attack are not all understood. There is investigative work needed before we shall know as much as we should about the etiology of the disease. However, we feel we have made a step ahead in that we understand some of the causes and can now obviate many of the features of the physiologic stasis associated with pregnancy.

There is also another factor which makes infection of the tract a little more frequent in the pregnant woman or in the parturient woman, and that is that the trauma of delivery necessarily affects the base of the bladder and probably makes the bladder more susceptible to infection. This background in a bladder which is atonic, which tends to overfill, requiring repeated catheterization in the puerperal period with the inevitable introduction of organisms with each passage of the catheter, certainly makes for a situation which is productive of a fairly high incidence of postpartum urinary tract infections. The incidence of pyelitis in pregnancy in New York is about 2 per cent in our experience.

We are particularly interested in treatment today so perhaps we had better give most of our attention to that phase of urinary tract infections in pregnancy.

The first thing which we ought to consider is prophylaxis. How can these urinary tract infections in the pregnant woman be obviated? There are certain prodromal symptoms which, if sought for when the patient comes for antepartum care, give a pretty good indication of impending upper urinary tract infection. Dysuria is frequent but a more common complaint is pain in the flank or even in the costovertebral angle of the right side. Often an intravenous pyelogram of a patient complaining of these symptoms demonstrates a high grade hydro-ureter and hydronephrosis of the type common in pregnancy. These symptoms can be controlled quite satisfactorily by having the patient lie down frequently, to take the weight of the uterus off the ureters. In addition the patient may be given a grain or 1½ grains of quinine one, two or three times a day.

More important, if there is dysuria and clumped pus cells in the urine, it is time to force fluids, alkalize the urine or use methenamine in an acid urine. I think it is fair to say that if it was possible to get every pregnant woman early in the pyelitis and give her this conservative care, one probably could abort a high proportion of primary cases of early pyelitis. That is not necessarily true of the chronic cases which are exacerbations of a previously existing urinary tract infection. We watch for both types in the antepartum clinic with a good deal of care and feel that we do abort a fairly good number of pyelitis cases in their incipience.

In a full blown upper urinary tract infection, with a hectic type of fever, what is to be done? The patient must go to bed; the horizontal position with drainage is just as important as ever. We find what the causative organism is because in our experience mandelic acid, as Dr. Stevens pointed out, is of very little use with the proteus type of organisms, but certainly with the aerogenes it should be used. With a proteus type of organism we use sulfanilamide. We prefer to use sulfanilamide for all other types of infection when the patient is in the hospital. On the other hand, if the patient is ambulatory, we still adhere to the use of mandelic acid except with the proteus organism.

There are several things to be observed in the patient who is actively febrile. In the first place, one must determine whether the infection is unilateral or bilateral. If it is bilateral one cannot afford to use palliative measures for months. What Dr. Stevens said about clearing up infections in the presence of obstructions is absolutely true. In pregnancy we can seldom clear the tract of infection during pregnancy. All we can do is to palliate, hold it in abeyance, and the real curative process must wait until after the pregnancy has been terminated and the obstruction removed. We are interested in bilateral infections because the inflammatory reaction going on over periods of months may produce damage in the mother which is out of proportion in its complications to the loss of the child. We always carefully evaluate these patients with bilateral involvement, particularly if there is a great loss in weight. If the infection does not yield after eight or ten days of conservative treatment, and particularly if the patient has a couple of months to go to reach term, we consider the advisability of interruption of pregnancy. We do not resort to it very often; however, the possible necessity is always in the back of our minds. The other thing we watch for particularly is involvement of the renal cortex. The earliest indicator we have of this complication is elevation of the nonprotein nitrogen in the blood. If this rises to above 50 mg. per hundred cubic centimeters we empty the uterus regardless of whether the lesions are bilateral or unilateral, because in our experience we have had great regrets when we have neglected the warning. The death rate in individuals who have a nonprotein nitrogen of over 50 mg. per hundred cubic centimeters—the normal in pregnancy is about 30 or 35—is about 25 per cent, a very high mortality.

We use mandelic acid in an acid urine exactly as has been outlined. With sulfanilamide therapy we like to administer 4 or 5 Gm. a day, always with sodium bicarbonate. We prefer not to give it to ambulatory patients but rather to get the patient into the hospital so as to force the treatment rather than to carry it out over a prolonged period. We have had very satisfactory results with both of these drugs.

In closing, I want to emphasize again that we do not cure patients of upper urinary tract infection during pregnancy. They must be followed afterward. The follow-up must be done in a cystoscope clinic, and sometimes it takes from three months to a year to eradicate the infection completely. The addition of mandelic acid and sulfanilamide to our armamentarium has helped very much.

If a patient has had pyelonephritis or bilateral upper urinary tract infection, we like to allow a year or two years to pass before pregnancy is again contemplated. We give contraceptive advice to these individuals, and if pregnancy does occur we hospitalize them and evaluate renal function before we allow pregnancy to progress. We are a little radical in our attitude because in bilateral pyelitis and in well authenticated pyelonephritis we have had very serious sequelae.

DR. CATTELL: Urinary infections present a common condition in children, and I will ask Dr. Levine if he will say something regarding the special problems which arise in connection with the treatment of urinary infections in infancy and childhood.

DR. SAMUEL Z. LEVINE: The general subject has been adequately covered. Perhaps we should define what we mean by urinary tract infection in childhood before we go on to a discussion of it.

Does urinary tract infection in childhood mean the presence of both pus and bacteria in the urine or may it be represented by a bacilluria in the absence of a pyuria? This still remains a moot question, but in routine catheterizations of thirty-four female infants under 2 years of age bacilli were found in 28 or 82 per cent of the urines in the absence of any white blood cells, indicating that bacilluria in infancy is a more common condition than we are prone to believe. In twenty-one cases B. coli was present in the urine in the absence of demonstrable infection of the urinary tract. The term pyuria should be limited to the persistent presence of clumps of pus in uncentrifuged, clean specimens of urine. Only these urinary observations represent a true urinary tract infection in childhood.

Of some interest is the question of terminology. At one time the name pyelitis was given to all types of urinary tract infection in children. There is no evidence at the present time to indicate that the entity pyelitis per se, inflammation of the pelvis of the kidney, in the absence of interstitial suppurative involvement of the kidney, is a common phenomenon. In most autopsies one finds in addition to the inflammation of the pelvis interstitial abscesses in the kidney parenchyma itself, so no longer do we use the term pyelitis but

prefer the terms acute and chronic pyuria, leaving the localization of the site of infection unnamed.

Urinary stasis probably plays as important a role in producing urinary tract infections in childhood as in pregnancy. Only rarely does one see a chronic or a recurrent pyuria in childhood in the absence of a congenital anomaly producing urinary stasis and secondary infection. If medical therapy is ineffective in overcoming the pyuria after a period of from four to six weeks, all children should be subjected to complete urologic examination. In over 90 per cent of chronic pyurias in childhood we find associated congenital anomalies.

In discussing the therapy, I shall also confine my remarks to the ketogenic diet, mandelic acid therapy and sulfanilamide.

Ketogenic diets are as unpalatable in childhood as they are in adult life.

Mandelic acid therapy is as effective in childhood as in adults. The dosage that we use aims to produce a urinary concentration of between 0.5 and 1 per cent and a reaction of less than 5.5 (p_H). If one gives approximately 1 Gm. of mandelic acid per excreted hundred cubic centimeters of urine, it should be within the required dosage. Since infants excrete about 400 to 600 cc. of urine a day, 4 Gm. of mandelic acid in divided dosage is usually adequate. Similarly, in children about 12 years of age who excrete around 1,200 to 1,500 cc. of urine, 12 Gm. of mandelic acid daily usually produces a urinary concentration of between 0.5 and 1 per cent. It is often necessary to use an accessory acidifier such as ammonium chloride in doses sometimes as high as from 2 to 8 Gm. daily to obtain the desired urinary p_H of 5.5 or less. It has been pointed out that mandelic acid therapy is ineffective in B. proteus infections. Similarly, one should not resort to the use of ammonium mandelate when one is dealing with organisms that liberate ammonia, like aerobacter or pyocyaneus. Sodium mandelate or calcium mandelate plus sodium acid phosphate are preferred in these types of infections.

Sulfanilamide, because it requires neither an acid ash diet nor restriction of fluid, and because it can be administered much more easily, is the choice of therapy in childhood except in the presence of infections due to Streptococcus faecalis, which are apparently resistant to sulfanilamide. The dose which we use in children is 0.2 Gm. per kilogram of body weight daily. We do not regularly use an alkalizer because we have found that if the urine is not too acid the sulfanilamide is almost as effective at a p_H of 6 as at a p_H of 7. The simplest way to test the p_H of the urine, whether we are using mandelic acid or sulfanilamide, is by means of chlorophenol red or nitrozine paper.

Finally, in using both mandelic acid and sulfanilamide, the drugs should be given for a minimal period of ten days to two weeks, even when the urine clears more rapidly than this, because the pyurias are prone to recur with shorter periods of therapy.

DR. MODELL: I should like to add one thing: I have listed on the board but failed to discuss the properties of the ideal urinary antiseptic. I merely wanted to mention that there is no such substance.

Properties of the ideal urinary antiseptic are rapid absorption from the intestine, rapid and continuous elimination in the urine, that it shall be nontoxic and nonirritant for human beings, effective against all bacteria, effective in alkaline and acid urine, active in the presence of obstruction, that it shall act from the renal pelvis down and that it shall be satisfactory in febrile states and in renal insufficiency.

DR. LEVINE: Dr. Traut, when you refer to the pyelitis of pregnancy, do you intend to imply disease of the renal pelvis alone?

DR. TRAUT: We just use it for old times' sake. We make the same objection to it that you do. However, we do not feel that we have as frequent involvement of the parenchyma of the kidney in the upper urinary tract infections in an adult woman as you would indicate was your experience with the chronic pyurias of children.

STUDENT: Are pyurias in children necessarily accompanied by parenchymal involvement?

DR. LEVINE: I did not mean to leave the impression without some reservation. In animal experimentation infections of the pelvis of the kidney have been produced in the absence of parenchymal involvement, but in the chronic pyurias and in many of the acute pyurias of childhood I think there is an associated pyelonephritis or a suppurative interstitial nephritis.

DR. JOHN E. DEITRICK: I should like to ask about the dosage of sulfanilamide when there has been involvement of the kidney. In a few cases I have seen, in which there was decreased renal function, if one gave sulfanilamide the amount in the blood rose rapidly, even when a small dose was used. No mention has been made about determining the blood level, which I feel is important if a patient has an elevated urea nitrogen or other evidence of inability of the kidney to function normally. We have seen toxic symptoms and found the blood level very high, although we had not reached a dosage ordinarily used in an adult person.

DR. STEVENS: I do not recall that I have had reason to employ the drug in a case with as marked renal involvement as described, but I remember that one of the articles by Helmholz records four or five patients with nonprotein nitrogen up around 50, 60, or even more, who excreted the sulfanilamide in large quantities, and that he obtained good clinical results in combating infections. The point has been made by various observers that one may expect more from that drug than from mandelic acid in individuals with poor renal function, as indicated by high nonprotein nitrogen or the high urea nitrogen in the blood.

DR. CATTELL: The universal distribution of sulfanilamide throughout all the cells and fluid of the body would suggest that it might be present in effective concentration as long as any urine was excreted.

DR. STEVENS: I think it has not been demonstrated how much of the efficiency of the drug in urinary infections comes from the excretion in the urine and how much comes through the body fluids. I did not mention the use of sulfanilamide in the treatment of gonorrhea; we did not have time for it. It has been found that as high a percentage of sulfanilamide may be found in the urethral pus as is found in the urine of the same individual, which I think is a very suggestive observation.

DR. HARRY GOLD: I notice that as urinary acidifying agents sodium acid phosphate and ammonium acid phosphate are being considered as interchangeable. I might call attention to the fact that a paper was presented at the federation last year in which a comparison was made between the urinary acidifying power of sodium acid phosphate and ammonium acid phosphate, and it was found that sodium acid phosphate in the usual

doses that are employed is much less effective as an acidifying agent than ammonium acid phosphate. Furthermore, ammonium acid phosphate is not very irritant to the gastrointestinal tract and can be used in very large doses, larger doses than sodium acid phosphate, without gastrointestinal symptoms.

DR. MODELL: There is a similar report by Alstead on the effect of ammonium acid phosphate, in which he stated that it was superior both to ammonium chloride and to acid sodium phosphate.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ABSTRACT AND APPRECIATION.

HOWARD A. CARTER, Secretary.

ABSTRACT OF MINUTES, MEETING OF COUNCIL ON PHYSICAL THERAPY, JANUARY 13-14, 1939

The Council on Physical Therapy held its annual meeting on Jan. 13-14, 1939, at the headquarters of the American Medical Association. The members present were Dr. Harry E. Mock, chairman, Drs. Anthony C. Cipollaro, William W. Coblentz, John S. Coulter, Arthur U. Desjardins, Walter E. Garrey, Howard T. Karsner, Frank H. Krusen, Frank R. Ober, Horatio B. Williams and Mr. Howard A. Carter, Secretary. Drs. Frank Dickson and Ralph Pemberton were unable to attend.

Dr. Mock was reelected chairman and Dr. Garrey vice chairman.

INTERFERENCE WITH RADIO COMMUNICATIONS BY ELECTROMEDICAL EQUIPMENT

A report was presented of an informal meeting held in New York, Jan. 9, 1939, at which representatives of the Federal Communications Commission and medical profession, specialists in the communication field and manufacturers of electromedical apparatus were present. It was the opinion of the committee reporting that a mutual understanding among the groups present had been reached. The committee reported that the engineers of the Federal Communications Commission and of the radio manufacturers demonstrated by the use of aural reception and television the effects of the interference of electromedical equipment. Although television has not been commercially practicable up to the present time, it was expected that television sets will be on sale during the summer and, in the opinion of the manufacturers of this equipment, interference by electromedical equipment might seriously retard the advancement of television. The members of the medical profession present at the meeting strongly emphasized the importance of electromedical equipment, especially electrosurgery in the treatment of cancer, diseases of the skin, and so on, and the use of medical diathermy in the treatment of those diseases in which internal heat is indicated.

Two solutions were proposed: (1) screening of the treatment room and (2) the allocation of radio bands or channels. The representatives of the radio industries felt that screening the treatment room was to be desired and that the cost might not be excessive. It was pointed out, however, by the physicians and manufacturers that the moving of surgical and medical diathermy equipment from place to place would be prohibitive and that the screening of an entire hospital or clinic would be almost impossible.

The alternative suggestion of allocating certain radio channels to the medical profession seemed to be the most suitable in view of the seeming impracticability of screening. The difficulty involved in the allocation of channels, however, seems to be that operating the equipment on a given frequency within certain toleration limits and keeping it on that frequency would increase the cost of the equipment. The Council was reminded that apparatus purchased and being used now would become obsolete unless time is allowed before regulations go into effect. The request, therefore, was made by the representatives of the medical profession that the same courtesy be shown to them as was granted the owners of ships equipped with radio apparatus of the spark gap type. Ship owners were allowed eight years from a certain date to liquidate the apparatus and to substitute more modern equipment. The suggestion was made, therefore, that the users of electromedical equipment already sold be allowed eight years to realize on their investment and that the manufacturer be given at least two years in which to change over and make new types available.

The accomplishments of this meeting were (1) a frank discussion of the problems of interference, (2) a visual demonstration of radio interference in television, (3) a presentation of the importance of electromedical equipment as used by the profession and (4) a mutual understanding of the problem involved. A committee of the Council was appointed to continue the study of this problem in an endeavor to cooperate with the interested bodies.

SHORT WAVE DIATHERMY

The Council voted to retain as one of its requirements for the consideration and acceptance of short wave diathermy apparatus the submission of six observations of the heating effects in the human thigh as observed by a thermocouple inserted before and after a twenty minute application of each technic promoted by the manufacturer. Acceptance is to be granted only to apparatus for technics the evidence for which has been submitted.

Minor changes in the manufacture of short wave apparatus, for example change in style of cabinet, nonessential revision in circuit or the substitution of more powerful thermionic tubes, as indicated by the lamp load test provided the temperature of the transformer does not rise beyond the safety point, is not to be considered sufficient alteration in design to warrant thermocouple-thigh test data being submitted for reacceptance.

Fundamental changes in circuit, reduction of power output as determined by lamp load test, promotion of different technic of application, change of frequency and fundamental changes in conversion of electrical energy to high frequency are to be considered important changes in the apparatus to warrant the submission of six observations of the temperatures in the human thigh as observed by the thermocouple for each technic of application recommended or promoted. For a recommended technic to be accepted, the final average temperature after twenty minute application of high frequency electrical energy shall be at least 103 degrees Fahrenheit in the deep tissues of the superior aspect of the human living thigh.

ORTHOPEDIC APPLIANCES

A discussion of problems with relation to the Council's consideration of orthopedic appliances, i. e. corsets, belts, supports and shoes, resulted in adoption of a motion to the effect that these appliances would not be considered by the Council after Jan. 1, 1940. It was decided, however, to sponsor the publication of several informative articles on the subject of shoes, corsets, trusses and abdominal supports.

AUDIOMETERS AND HEARING AIDS

A review of the Council's work in the consideration of audiometers and hearing aids was presented, and after some discussion it was generally agreed that the Council will continue its consideration of audiometers without restriction of advertising until further study is made in the field. The Council will continue to consider hearing aids and prepare reports for publication in THE JOURNAL.

ROENTGEN RAYS

The Council discussed ways and means of continuing its consideration of roentgen ray apparatus. It was agreed that cooperation with other interested bodies would have to be secured before the Council could proceed with its investigations.

RADIUM AND RADON

It was pointed out that the House of Delegates had adopted a resolution presented by the Judicial Council at the annual session of the American Medical Association in 1938, condemning the practice of renting radium to unqualified physicians. The Council therefore adopted the following resolution:

WHEREAS, The Council on Physical Therapy has long been opposed to the practice of indiscriminate rental of radium or sale of radon by certain commercial firms and private physicians, who, possessing radium, undertake to supply radium or radon to any physician who may apply,

regardless of his special training and experience in its use, and who even furnish instruments and instructions without having seen or examined the patient, and

WHEREAS This constitutes the practice of medicine by mail or by telephone, and

WHEREAS Four years ago the Council on Physical Therapy passed a resolution condemning this practice but, when this resolution was submitted to the Board of Trustees of the American Medical Association for approval the Board of Trustees voted against it, and

WHEREAS During the past year, at the instigation of Dr Edward H Skinner (Kansas City) the House of Delegates of the American Medical Association passed an essentially similar resolution which had been presented by the Judicial Council and confirmed by the Board of Trustees, and

WHEREAS This action implies that, since the American Medical Association has officially condemned the practice the columns of THE JOURNAL (and indirectly the columns of most of the journals of the state medical societies) should be closed to any advertising that would tend to foster the practice, be it

Resolved That the Council on Physical Therapy is deeply gratified by and heartily approves the action of the House of Delegates of the Judicial Council and of the Board of Trustees The Council stands ready to investigate the products review the advertising and as part of its duty, make this information available to THE JOURNAL

It was also agreed to arrange for the preparation of a series of Council articles on the dangers of the indiscriminate use of radium

RESEARCH

The Council considers problems of merit in research and believes that there are a number of subjects of vital importance in the application of physical agents to the treatment of disease worthy of investigation, and that investigations of such subjects would lead to important contributions to the practice of physical therapy During the year 1938, one grant was awarded for research

EDUCATION

A lengthy report of the activities of the various Council members and consultants in this field was presented It was suggested that articles be published during the coming year on the following subjects spastic paralysis, peripheral nerve injuries, the abuse of medical diathermy, the injudicious use of radium, the use of corsets, abdominal belts and trusses, and the effect of ultraviolet radiation on the production of cutaneous cancer

APPARATUS ACCEPTED, THE COUNCIL'S PUBLICATION

The members of the Council expressed the opinion that the use of diathermy and other methods of producing heat within the tissues is being greatly overrated and abused, and that too much emphasis is being given to machine therapy The Council believes that the profession should be informed of these abuses by means of a Council article pointing out that other methods of physical therapy are of greater importance, for example the intelligent management of the patient, the proper use of therapeutic exercise, massage and hydrotherapy

After some discussion concerning the booklet "Apparatus Accepted," action was taken to initiate a review of the booklet with the idea of revising it to increase the amount of information to the general practitioner concerning the value of the various accepted devices

EXHIBITS

Plans for the exhibit at the annual session of the American Medical Association in St Louis were considered

Suggestions were also advanced concerning the Council's proposed exhibit on the management and treatment of lame backs It was agreed that if such an exhibit is approved a film on this subject should also be prepared to be shown at the same time

NOMENCLATURE AND DEFINITION

A report was made to the effect that work on the definitions is now being carried on and that considerable progress is being made in this line

PRESENT STATUS OF PHYSICAL THERAPY

The committee assigned to revise the Council's report on the present status of physical therapy announced that work is progressing in this direction and that a report would be made available during the coming year

AN APPRECIATION

The Council wishes to acknowledge with deepest appreciation the valuable assistance rendered by the following in connection with the work of the Council

Drs Fred Adair, M Herbert Barker, H C Bazett, Robert Bennett, William Bierman, Earl Bond, Walter Boothby, R C Burt, A J Carlson, J Marion Clamplt, Eliot R Clark, Milton B Cohen, Geza de Takats, Earl C Elkins, F H Ewerhardt, G K Fenn, A Bruce Gill, F B Gordon, Allan Hemingway, John S Hibben, K K Jones, Louis Katz, Disraeli Kobak, Henry Laurens, Arno Luckhardt, George Miller MacKee, Gilbert Marquardt, Albert Martucci, C O Molander, Tell Nelson, John R Pribble, E M Smith Jr, K W Stenstrom, Grant E Ward, Francis Carter Wood and Mr S L Osborne

Artificial Limbs—Drs Paul Steele and Philip Wilson and Messrs William Herman, W E Isle, George M Morris, J V Sprevak and James Waltz

Audiometers and Hearing Aids—Drs C C Bunch, George M Coates, L W Dean, E P Fowler, Henry Hartig, Austin Hayden, Isaac Jones, Douglas Macfarlan, Horace Newhart, B R Shurly and W P Wherry

Educational Work—Drs Richard Dillehunt, Bernard Fantus, A J Kotkis, Richard Kovacs, Franklin P Lowry and William Schmidt

Ophthalmologic Devices—Drs Francis Heed Adler, Charles A Bahn, S Judd Beach, William L Benedict, Conrad Berens Alfred Cowan, John Evans, Jonas Friedenwald, Sanford Gifford Walter B Lancaster, William H Luedde, John MacNie and Clifford B Walker

Roentgen Ray and Radium—Drs L F Curtiss, William E Chamberlain, Arthur C Christie, Edwin C Ernst, Gioaochino Failla, Thomas A Groover, Fred M Hodges, George Winslow Holmes, John T Murphy, Robert Reid Newell, E P Pendergrass, George Pfahler, U V Portman, Lauriston Taylor and J F Weatherwax

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH, Secretary

SOLUTION LIVER EXTRACT PURIFIED-LILLY.—A sterile aqueous solution of liver extract purified preserved with 0 5 per cent phenol, containing 15 U S P units per cubic centimeter

Actions and Uses—Solution liver extract purified-Lilly is proposed for intramuscular injection in the treatment of pernicious anemia See general article Liver and Stomach Preparations, New and Nonofficial Remedies, 1938, page 321

Dosage—For the average patient in relapse, treatment may be instituted with an initial dose of 2 cc (30 U S P units), or 1 cc (15 U S P units) may be given on two successive days, then a weekly dose of 1 cc (15 U S P units) may be given until the red blood cell count and blood hemoglobin have reached satisfactory levels

For maintenance of the average patient 1 cc (15 U S P units) is adequate at fifteen day intervals Especially close laboratory follow-up is indicated whenever the physician takes the responsibility of administering an average daily dose of less than 1 U S P unit

Manufactured by Eli Lilly & Co, Indianapolis Ind No U S patent or trademark

Ampoule Solution Liver Extract Purified Lilly 1 cc Each cubic centimeter contains 15 U S P units Marketed in packages of three 1 cc rubber stoppered ampules

To prepare purified solution liver extract Lilly, livers from edible animals are ground directly into water, and the mixture adjusted to the isoelectric point (approximately pH 5 to pH 6) The mixture is then heated to coagulate proteins (approximately 80 C) stirred for several minutes and filtered The filtrate is reduced in vacuum to a small volume and enough 95 per cent alcohol added to produce a concentration of approximately 70 per cent The precipitate which is formed is discarded and the filtrate reduced to a small volume much of the total solids remaining at this point is removed by treatment with ammonium sulfate zinc sulfate and alcohol yielding a product which is highly potent and which contains only a small amount of solids The final product is in the form of a water solution containing 0 5 per cent of phenol

TRAUMA AND DIABETES

The concept of traumatic diabetes virtually began with Claude Bernard's diabetic puncture. In the earlier literature, which is fairly extensive, appears a report by Asher, who assembled 124 cases and concluded that one was not justified in establishing a causal connection between trauma and diabetes by pathologic changes and physiologic results. Traumatic neurosis was introduced by Ebstein in 1892. A traumatic origin of diabetes was recognized by von Noorden in 1898. In general, authors considered that traumatic diabetes actually existed and that it was a neurogenic diabetes due to trauma in the central nervous system.

Somewhat later Stern felt that clinical observations gave rise to doubts because of the possibility that diabetes was present before the trauma and because the diabetes following trauma is indistinguishable from the diabetes occurring otherwise. Lépine thought that trauma must be considered in 5 per cent of cases of diabetes although noting too the question of hereditary predisposition. Naunyn favored the idea of a traumatic factor and presented eight cases of his own in which diabetes occurred after trauma of the head as well as after noncerebral trauma and traumatic neurosis. Welz in 1915 emphasized that the probability of a relationship between trauma and the disease decreased in the symptom-free interval, placing the limit at from two to three years. As late as 1912 von Noorden still believed in the presence of acute glycosuria of nervous origin but felt that it was doubtful or even impossible that genuine chronic diabetes could persist as a result of a nervous disturbance without the pancreas being affected. Kausch denied the etiologic importance of trauma and raised the objection that in all the reported cases the disease existed before the trauma.

After the World War von Noorden pointed out that it had been an enormous tax on the nervous system, a mighty and terrible physical experiment which must clear up the question whether the notion of chronic neurogenic diabetes and so-called traumatic diabetes shall henceforth be reckoned with. Finally, he concluded that the soldiers who incurred diabetes during the war took the field as men with masked diabetes, whose disease as a rule was merely accelerated. His opinion was shared by Albu, Gottstein, Umber and Hermann Strauss. Lenné differed, relating the disease to physical and psychic strain, but admitted that injuries and diseases have no essential influence on the appearance and character of the disease. Umber agreed with von Noorden and in 1927 declared that no experimental or clinical evidence existed that an injury to the brain, head, trunk or extremities could cause diabetes and that to explain the diabetes one must find diminution in the function of the pancreas. True traumatic diabetes could not be thought to appear unless the pancreas itself was severely injured, because experiments have shown that at least four fifths of the pancreas must be removed before diabetes appears. However, such severe trauma as a rule will lead to death. He considered that the aggravation of diabetes by trauma as a rule is negligible and that, in the majority of cases, it can be suppressed by adequate treatment; nor does it give rise to any persistent change in the future course. Later he emphasized the general hereditary disposition in 26.4 per cent of cases and cited Danforth to the effect that in cases of recessive heredity 72 per cent of the diabetic need not have any diabetic relatives, comprising siblings, parents and their siblings and grandparents, during three generations. Hence it will almost never be possible to exclude definitely the existence of diabetic genes. Umber agreed with von Noorden, who in 1923 stated unequivocably that neurogenic diabetes does not exist, the experiences of the war having put it completely in the grave.

Isaac acknowledges a causal relationship if the diabetes comes on within four weeks after the trauma and Grote agrees that a longer interim renders a causal relationship unlikely. Stern says that a causal relationship is probable only (1) if there are no indications of an earlier existence of diabetes, (2) if the accident has caused a lesion of the pancreas or the central nervous system and (3) if diabetes develops during the first weeks after the accident.

Examinations of the blood sugar were first mentioned in 1915. Dextrose tolerance tests were few and the results difficult to compare because of lack of uniformity. A cerebral concussion is more important in producing hyperglycemia than a cranial fracture.

Thomsen [1] has just made available the only monograph in English on this subject. He examined 100 patients with regard to spontaneous as well as alimentary hyperglycemia and glycosuria at the time of accidents. Blood tests were done on ninety-four of 100 patients, both during fasting and after administration of dextrose, within three days after the accident. His material consisted of 144 patients, forty-four of whom were not given dextrose tolerance tests. Age was important.

1. Thomsen, Viggo: Studies of Trauma and Carbohydrate Metabolism with Special Reference to the Existence of Traumatic Diabetes, Acta med. Scandinav., supplement 91, 1938.

Disturbances in carbohydrate metabolism immediately after the trauma are much more frequent under than over the age of 30, although they are more transitory in the young than in the old. While there are disturbances of carbohydrate metabolism in a considerable number of patients, the distribution of the types of physical trauma into groups shows that no decisive importance can be attributed to the kind and location of the trauma, whether cerebral, peripheral or otherwise, with regard to the frequency and intensity of the detected disturbances.

An increase of the fasting blood sugar was found in twenty-four cases, that is in 17.5 per cent of all the cases. Abnormal dextrose tolerance curves were obtained in thirty-four of 100 cases. In the majority the glycosuria was detected in the portions of urine voided shortly after admission. Sugar was thus found in twenty of thirty-four specimens. In isolated cases it persisted more than seven days; in one, after a sugar-free interim, it contained sugar on the fifteenth day. One patient had renal glycosuria. The glycosuria was usually slight; in only twelve cases was the value above 0.5 per cent. There was no polyuria. In ten cases in which dextrose tolerance tests were performed there was diabetes in the immediate family. Thomsen concluded that no importance could be ascribed to the disturbances of carbohydrate metabolism detected after trauma. The duration of such disturbances, even with the most persistent spontaneous hyperglycemia, based on the fasting blood sugar level, was five days. Dextrose tolerance curves were abnormal once or several times, but in twenty-four cases the abnormal curves were detected only at the first examination, performed within three days after the accident. Fifteen patients, reexamined from three to twenty-nine days after the trauma, presented normal conditions. In one case a disturbance of the carbohydrate metabolism was disclosed by an abnormal dextrose tolerance curve as late as forty-nine days after the accident, while two patients who presented abnormal curves after a lapse of thirty and forty-nine days respectively had a normal curve ninety-seventy and 144 days after the trauma. In none of the patients who survived the accident did diabetes occur in close sequel to it, and this must be supposed to apply also to those patients who died shortly after the accident. The duration of the disturbance in carbohydrate metabolism as well as its frequency was greatest in the higher age groups. In forty-seven of fifty cases a second examination was performed from six to thirty-eight months after the accident. In none of these had diabetes occurred, and in two of the remaining three nothing is known concerning the occurrence of diabetes up to three and one-half years after the accident. One patient was untraced.

To answer von Noorden's question as to whether diabetes is more frequent in persons who have met with accidents than in noninjured persons of the same age and standard of living, Thomsen investigated the material of the district hospital in Aarhus, Denmark, where he was assistant physician. From 1921 to 1935 there was scarcely any difference in the frequency of diabetes in injured and noninjured patients of the same age and standard of life. Thomsen says that he has not seen the description of any case of existing diabetes in which trauma has been proved to have given rise to a permanent change in the degree and course of the disease. In his opinion the trauma, strictly speaking, cannot be incriminated for an indirect exacerbation of diabetes, such as is due to lack of exercise, change in diet, or to the accompanying infection, and such an exacerbation must be disregarded in order to afford an idea of a traumatic exacerbation proper of the diabetes.

From an analysis of 100 cases he finally concludes that in the case of existing diabetes trauma can give rise to an exacerbation, though of a temporary nature. Temporary exacerbation ensues in about half the cases. The exacerbation is independent of the kind and location of the trauma. It appears immediately after the accident and has an average duration of twenty-six days. His studies afforded no evidence that trauma gives rise to a later exacerbation of the disease. It very probably is able to provoke coma only in a predisposed person who has severe diabetes. The effects might be compared with those produced by a stone thrown into a brimful vessel, which it causes to flow over, and a stone thrown into another, not brimful, vessel, in which it merely produces a ripple on the surface of the water.

Does the course of diabetes which occurs or is exacerbated after trauma differ markedly from the course of similar conditions of metabolism? Thomsen points out that, it being so difficult to compare one diabetic person with another, it must be much more difficult to draw reliable conclusions as to whether the patient under consideration would present a different picture if the trauma had not occurred. He then assembles eighty-one cases in which trauma has been reported as a factor in the appearance of the diabetes. One would expect, he says, quoting Joslin, that the age at the onset of the disease would have been under 40 in 38 per cent and above 40 in 62 per cent, and, he asks, should the trauma give rise to diabetes sooner in the younger than in the older patients? Apparently of injured normal persons 72 per cent were below and 28 per cent above 40. Males in this group predominated, 85 per cent, females 15 per cent, instead of Joslin's 64 per cent of females among the diabetic generally. The onset was indefinite in 43.2, gradual in 37, rapid in 14.8 and sudden in 5 per cent. His conclusion is that reported "traumatic" diabetes usually occurs in younger persons, is to a considerable extent a disease of males and behaves in onset and course like ordinary diabetes. Thus with regard only to age and sex was a deviation from ordinary diabetes detected. This deviation depends not on any special mode of

reaction to trauma in young males but merely on the fact that such persons incur injuries with correspondingly greater frequency. Hence the detected deviation cannot be utilized for the assumption of an essential difference between so-called traumatic and ordinary diabetes.

The post-traumatic disturbances of the carbohydrate metabolism detected in human beings by Thomsen's investigations are brought about by reflexes via the sympathetic nervous system. He based this conclusion on tests with ergotamine and considered that these were substantiated by experiments reported on animals.

In the chapter "Does Traumatic Diabetes Exist?" he states that in human beings neither "experimental" nor clinical clues were found to warrant the assumption that post-traumatic sympathicogenic disturbances in the carbohydrate metabolism can lead to diabetes. His own investigations showed that the disturbances of carbohydrate metabolism were always transitory and that subsequent examinations did not reveal diabetes in any of the cases, and he asserts that "traumatic" diabetes does not differ from ordinary diabetes with regard either to existing disposition or to its mode of onset or further course. An examination of the histories of diabetic and nondiabetic persons of the same age and mode of living reveals no difference in the incidence of head trauma and that there is no reason to assume that diabetes is more frequent in injured than in noninjured persons. As to whether trauma can activate latent diabetes, he states that it is apt to cause an exacerbation of existing diabetes, but only a temporary exacerbation, and that there is no evidence of any subsequent exacerbation. Therefore physical trauma cannot be assumed to evoke latent diabetes, at any rate in any other way than that, after the cessation of the effects of the trauma, again one is dealing with latent diabetes. He admits that, theoretically, trauma is able to make a latent diabetic condition manifest. Since diabetes is of no greater incidence after trauma than after other surgical conditions necessitating hospitalization, there is no reason to consider traumas of greater importance as causal factors of the detected diabetes than the other surgical complaints. Pancreatic diabetes is the only form of diabetes the existence of which has been proved by animal experiments, wherefore it must be considered established that trauma giving rise to as extensive a destruction of the pancreas as that required by experiment will be followed by diabetes, and he considers that no such cases have been reported. He excludes Wells's case. He was not conversant with the case from Gräfe's clinic cited by Joslin. Thomsen's monograph was completed before the work of Young in London, who produced permanent diabetes experimentally by injection of pituitary extract.

This work, supported in part by the Norwegian Insulin Fund, is a real contribution to the problem of trauma in relation to diabetes.

FUMIGATION WITH HYDROGEN CYANIDE

Evidence of the superior efficacy of hydrogen cyanide as a fumigant for ships and houses has been rapidly accumulating. As this method becomes applied more extensively, the problems of toxicity and ventilation following use have received special study. After the employment of hydrocyanic acid gas as a fumigant for ships in the tropics, with the technic which has been developed, Gilles [1] states that the average time for clearance of the gas after fumigation has never exceeded six hours. At the expiration of four hours' continued ventilation, the holds and spaces are carefully tested with methyl orange or copper benzidine acetate test paper. When the fumigated space is found clear of dangerous quantities of gas, the crew is allowed on board and, under supervision, all pillows, blankets, mattresses and the like are brought out, hung and aired in the sun. Gilles does not report any toxic effects to the crew from this procedure.

Etteldorf [2] conducted accurate determination of the critical concentration of hydrocyanic acid on twenty-two dogs, seven rabbits, four guinea pigs, five white rats and four chickens and investigated whether the effective and recognized method of detoxification could be exhausted by subjecting dogs to single and repeated dosages of hydrocyanic acid for periods ranging up to eight and twelve hours. He also studied the antidotal and prophylactic value of methylene blue against gaseous hydrocyanic poisoning. The critical level for each species of animal was measured and demonstrated by the onset of convulsions. Below the critical level, hydrocyanic acid is sufficiently controlled for an unlimited time by the detoxifying mechanism of the animal. Evidence of tolerance or increased susceptibility was not obtained. Methylene blue had little value as treatment above the critical level of cyanide poisoning but was valuable as a prophylactic against these concentrations.

Perhaps the most important problem from the practical point of view is the method of ventilation following hydrogen cyanide fumigation. Page and his colleagues [3] investigated this aspect in a series of careful observations in English houses of various types and age and under different weather conditions. Their conclusions in part were that all windows should be kept open for twenty-four hours after fumigation, unless this leads to the entry of rain or snow. A ventilation period of this length is generally sufficient for an empty house of normal construction, but a longer period may be required for a furnished house or for a house which is damp, which contains an unusual proportion of dead space or which contains rooms without windows providing adequate communi-

cation with the open air. They conclude that fumigation of clothing, and particularly bedding, as a regular practice is undesirable. Further, upholstered furniture should be placed in a position to facilitate airing; the customary tests with benzidine acetate-copper acetate should be made (a blue color in all air spaces indicating a concentration of one one-hundredth or less per thousand cubic feet gives a margin of safety). If the house contains much absorbent material or if any other circumstances suggest that a period of twenty-four hours of airing may not be sufficient, all doors and windows should be closed after performing the tests with benzidine acetate-copper acetate and these tests should be repeated after the house has remained closed for two hours.

Supervision of fumigation is a public health problem. For example, in New York, fifty-three concerns hold permits to conduct the business of fumigation and extermination. From June 1, 1936, to June 1, 1937, there were, according to Oberwager,[4] 353 fumigations performed in that city under the supervision of the sanitary bureau of the health department. In fact the New York regulations governing fumigations have been changed recently to provide for additional safeguards for the occupants of premises during and following fumigation.

Current Comment

THE ABORTIFACIENT AND OTHER EFFECTS OF THE URINE AND SERUM OF CANCEROUS PATIENTS

Elsasser and Wallace[1] recently reported that the urine and serum of patients with malignant tumors have a selective action on embryonal or newly growing tissue. The work began with the urine of a man with an embryonic cancer of the right testicle. Daily intravenous injections in pregnant rabbits of 20 cc. of urine produced abortion on the fifth day. The urine of patients with other tumors of embryonal nature—dysgerminoma of the ovary, teratoma of the testicle, Wilms tumor—produced abortion, as did "the urine of a large number of patients with other types of malignant tumors" (no further details are given). The blood serum of patients whose urine caused abortion also was effective. Control tests with the urine or serum of normal persons and of noncancerous ward patients gave negative results. Following the daily injections of urine from cancerous patients a progressive placental necrosis with infiltration of inflammatory cells occurred, with destruction of the embryo or expulsion in late pregnancy. In nonpregnant rabbits the injections of urine caused degeneration of the graafian follicles and sclerosis of the ovarian tissue; in male rabbits the injections caused degeneration of the spermatogenic processes. In rats with implanted carcinoma (Walker 256) injection of urine from cancer patients was followed by necrosis of the carcinomatous as well as of newly formed blood vessels. Here it should be noted that the urine of pregnant women did not cause abortion in rabbits and neither did massive doses of anterior pituitary-like preparation [2] together with estrogenic hormone. Many problems arise from these interesting results which call for further work along various lines. The results of such work will be awaited with keen interest. Whether the principle has been discovered of a test of value in the early diagnosis of any kind of cancer remains to be determined.

RENAL CALCULI IN VITAMIN A DEFICIENCY

The occurrence of urinary calculi in rats fed on a diet deficient in the fat-soluble vitamins was first reported by Osborne, Mendel and Ferry.[1] Through numerous repetitions of this type of experiment the role of vitamin A in experimental urolithiasis has been recognized but the mechanism of stone formation under these conditions is not entirely clear. Thus the alkalinity of the urine excreted by rats on a vitamin A deficient diet has been related to stone formation by some investigators and the infection of the urinary tract resulting from vitamin A deficiency is believed to be an important contributory factor by others. A recent report of Steiner, Zuger and Kramer [2] on the production of renal and ureteral calculi in guinea pigs by feeding these animals a diet deficient in vitamin A is of particular interest as the alkalinity of the urine alone and infection of the urinary tract apparently did not have an important part in the development of the concretions. Large plaques of desquamated epithelial cells were found in the pelvis and ureters and it appears that these large plaques acted as niduses for the formation of calculi. There was no gross or microscopic evidence of infection in the urinary tract. The transformation of epithelial cells which has been recently dealt with by Wolbach [3] was observed. The vitamin A deficiency caused hyperplasia, later metaplasia to squamous epithelium, and finally atrophy of the pelvic and ureteral mucosa. The observations of Steiner and his collaborators do not minimize the importance of improper mineral balance of the food, presence of infections in the urinary tract and excessive alkalinity of the urine, other factors which may be involved in the genesis of urinary calculi as a result of faulty diet. The detailed description of the part played by small pieces of epithelium in the production of calculi in the guinea pig in these particular experiments sheds more light on the etiology of urolithiasis, a subject which long has needed clarification.

ORGANIZATION SECTION

THE WAGNER BILL

AN ANALYSIS OF THE WAGNER NATIONAL HEALTH BILL OF 1939

J. N. BAKER, M.D.
Member, House of Delegates, American Medical Association,
and Alabama State Health Officer
MONTGOMERY, ALA.

Just a few weeks ago—on February 28, to be exact—the senior Senator from New York, Hon. Robert F. Wagner, introduced in Congress a measure of far-reaching importance to the people of the United States and particularly to the people of the South. This measure, known as the National Health Act of 1939, has been referred to the Senate Committee on Education and Labor and is now awaiting action by that committee and later by the two houses of Congress.

The chief purpose of this measure, as described in its preamble, is "to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health service, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance," and so on.

More specifically, the measure makes use of the sound procedure of grants-in-aid to the various states, which provides a wide latitude to the individual states in the development of their own health plans, conditioned by the particular health problems of greatest importance to their own people. Such grants-in-aid are provided for the purpose of establishing, expanding and improving state programs in the fields of child and maternal health, general public health services and investigations, construction of hospitals and health centers in communities where they are most needed, general medical care, and insurance against loss of wages and salaries during periods of temporary disability. Administration of the act, if it is passed in its present form, will become the responsibility of three already established federal agencies: the Children's Bureau, the United States Public Health Service and the Social Security Board. In discussing the bill at the time of its introduction, its sponsor declared that "the fullest development of this program would bring the benefits of modern medical science, both preventive and curative, within the reach of all groups of the population, especially in rural areas suffering from economic distress." In view of the fact that such a large percentage of the people of the South are residents of rural sections and the even more significant fact that they rank extremely low in per capita wealth, the National Health Act of 1939 promises to make available to the people of this state a degree of medical, nursing and hospital care never known in the past.

It has been pointed out that under no circumstances will the federal government undertake to furnish medical care. Administration in all cases, except of course in the matter of the necessary federal allocation of funds and insistence on states complying with the proper standards of performance, will be through the states, which will formulate their plans on the basis of local needs, conditions and problems. No attempt will be made to displace existing activities with new ones, although naturally these activities will be able, with additional funds, to expand and to operate much more effectively.

No system of health insurance is contemplated in the bill as a function of the federal government, nor is any participating state required to institute such a system. In that section of the measure dealing with a general program of medical care (title XIII) the states will be at complete liberty to develop, under the inspiration of local needs, conditions and problems, the types of medical care programs they peculiarly need, subject of course to the proviso that the programs devised must square with certain basic standards to be set by the three federal agencies that have been mentioned. The general program of medical care which a particular state may formulate as best for its own people may be limited, at the discretion of its officials, to persons on relief or, again at their discretion, it may be broadened to include those of nonrelief status. It may be financed entirely by insurance contributions, from tax funds or from both. The method and scope of medical services to be provided likewise are to be determined by the proper officials of the state concerned and, of course, these services may be provided by private agencies and institutions already in operation, if that is desired. Provision is wisely made for the training of personnel employed to provide these services, and such personnel must be selected on a merit basis.

An important aspect of the bill which should not be lost sight of is the absence of specific detail for operation incorporated into the basic law. Such specificities would have destroyed the autonomy of states in the effort of each to work out its own salvation in a yet uncharted field.

The act carries appropriations totaling approximately $80,000,000 for the first year, exclusive of such sums as Congress at its discretion may appropriate for aiding the states in the construction of needed tuberculosis sanatoriums and mental hospitals, with increases from year to year over a ten year period. Under its terms federal appropriations would be available for the matching of sums appropriated by the individual states as their share of the cost of their own health programs. The measure carries no authorization of new federal payroll taxes.

In order to accomplish one of the main purposes of the measure, namely the aiding of economically impoverished communities in their efforts to provide needed hospital, medical and nursing care, the measure stipulates that the federal funds appropriated to put it into effect are to be allocated to the several states on a variable matching basis, the amount to be received by a particular state depending on that state's relative financial resources, as determined by the per capita income of its

population. Thus the bill is intended by its sponsor and supporters to "raise the general level of health protection throughout the country, while reducing the existing wide variations among the states, and especially as between rural and urban areas."

In addition to the health services in the preventive and curative fields already mentioned, the bill provides grants-in-aid to the states to be used in setting up insurance plans by means of which cash benefits may be made available during periods of temporary disability. Such systems would be so devised as to provide the greatest possible protection to the American wage earner against wage loss resulting from such disability, which loss is estimated at more than a billion dollars a year. Thus systematic insurance payments would insure the continuance of workers' incomes through those periods when they are most needed.

The National Health Act of 1939 is not intended to transform the United States into a utopia in health matters overnight. However, it was framed and introduced in the hope and belief that it would bring the blessings of health protection to multiplied millions of our people whose need for such protection is no less great because as a result of their financial status they have not been able or, at best, have been only partially able, to finance it in the past.

BUREAU OF MEDICAL ECONOMICS

The article by Dr. J. N. Baker was submitted to the Bureau of Medical Economics of the American Medical Association, which submits the following comment:

The basic questions raised in connection with the Wagner bill are probably the following two: first, whether the proposed appropriations for the various purposes are suitable to the needs; second, whether the bill, by extending federal help or subsidies, is intended to encourage the establishment of sickness insurance systems by states.

This discussion appears to assume that the federal allocation of funds will actually be made "through the states, which will formulate their plans on the basis of local needs, conditions and problems."

It also states that "no system of health insurance is contemplated in the bill as a function of the federal government," which is probably a correct statement. But, if federal subsidies are to be used to encourage states to adopt such plans, then it is to that extent a sickness insurance bill providing for partial support by the federal government.

Is "the absence of specific detail for operation" in the basic law wholly desirable if the effect of the law is to subsidize plans the "specific detail" of which would be determined largely by the federal authorities?

BUREAU OF LEGAL MEDICINE AND LEGISLATION

Dr. Baker's statement was submitted also to the Bureau of Legal Medicine and Medical Legislation, which submits the following comment:

Dr. Baker's analysis is entitled to careful consideration not only because of his professional and official standing but also because it presents a view of Senator Wagner's proposed amendments to the Social Security Act that seems to be based largely on local considerations and on economic conditions that every one hopes are only temporary.

The bill introduced by Senator Wagner, S. 1620, is described in its title as "A Bill to provide for the general welfare by enabling the several States to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance, and training of personnel; to amend the Social Security Act; and for other purposes." Of this bill, Dr. Baker says:

> In view of the fact that such a large percentage of the people of the South are residents of rural sections and the even more significant fact that they rank extremely low in per capita wealth, the National Health Act of 1939 promises to make available to the people of this state [Alabama] a degree of medical, nursing and hospital care never known in the past.

To accomplish this result—

> . . . the measure makes use of the sound procedure of grants-in-aid to the various states, which provides a wide latitude to the individual states in the development of their own health plans, conditioned by the particular health problems of greatest importance to their own people.

The arguments advanced by Dr. Baker in support of the amendments to the Social Security Act, proposed by Senator Wagner, have a certain degree of validity. They must be weighed, however, in the light of his status as the health officer of a great state, but a state whose people happen just now to be in financial distress and in need of help. Speaking for the country over, one might reply to Dr. Baker's arguments along the following lines:

The term "grants-in-aid" implies that the federal government will pay to the several states, or to some of them, money to aid in carrying on certain intrastate activities. Such a grant, however, is generally made only on condition that the state appropriate state funds to help defray the cost of such activities and always on condition that it submit to certain conditions imposed by the federal government, including the supervision and control of the work by federal officers. Waiving all question as to the essential soundness of such federal grants, in a country such as ours, organized under a constitution carefully designed to preserve the rights of the several states from infringement by the federal government, a brief examination of the operation of such grants seems to show not only that the underlying principle is essentially unsound but also that, instead of enabling the several states to make more adequate provision for public health and such other activities described in the caption of the Wagner bill, they tend to limit the ability of many states to do so.

In the first place, we must ask where the federal government is to obtain the money wherewith to pay such grants-in-aid as are proposed in this bill. The federal government cannot create money and it must get it somewhere. It can get it only by taxation, and the ultimate consumer pays the price in the cost of living. Conceivably it might abandon governmental activities already under way and apply to the new projects proposed by Senator Wagner the money thus saved. On the other hand, it might and presumably will levy additional taxes if the bill should be enacted.

No proponent of the Wagner bill has even as much as suggested that any federal activity now under way be curtailed or abandoned to provide the funds necessary to pay the federal share of the expenses of the activities proposed by Senator Wagner. The abandonment of any such activity, however, would still leave the cost to be paid out of the taxes thereby rendered unnecessary and which might be discontinued but for the enactment

of this bill. It is generally assumed, however, that the money for the federal share of the expenses of the proposed activities will be provided by additional taxes, if the bill is enacted. As the bill now stands, it does not propose to levy additional taxes in the form of federal payroll taxes or specific taxes of any kind, having direct reference to the expenses of this legislation; for any proposal to levy taxes for that specific purpose would bring to the attention of the taxpayers of the country the cost of the pending bill and probably insure its defeat. The needed money, therefore, must presumably be raised by increasing the rates at which some of our existing taxes are levied or by imposing new general taxes of some kind, and the taxpayer, even though he may complain of the increase in taxation, will not be able to associate the increase with the cost of this bill. And the primary taxpayer—that is, the taxpayer who pays the money directly into the federal treasury—will whenever he can pass the tax along and sooner or later it will rest on the back of the ultimate consumer, whose ability to maintain himself and his dependents will be decreased in proportion to the increase in taxation.

But that is not all. Grants-in-aid given by the federal government will generally have to be matched wholly or in part by money provided by the several states to which such grants are made. The state accepting a grant-in-aid will find itself, therefore, in the same position as that of the federal government; it will have to curtail or discontinue present activities and public benefits in order to obtain the money wherewith to meet the federal grant or else will have to increase state taxes. If the state activities curtailed or discontinued are essential to the public welfare, the public will suffer. If new taxes are imposed or the rates of taxation with respect to old taxes increased, the increase in the tax burden will reach the ultimate consumer, with corresponding further increase in his cost of living and with further diminution in his ability to provide support for himself and his dependents.

There is another aspect of the grant-in-aid system such as Senator Wagner's bill proposes that is seldom recognized. Even though it may enable some states to make more adequate provision for projects covered by the act, it lessens the ability of other states to do so. With respect to states in the latter class, so-called grants-in-aid are not "in-aid" but are only the return by the federal government to the state of money taken from its people through federal taxation, directly or indirectly, and even that return is made only on condition that the state submit to the determination by the federal government as to the purposes for which it shall be spent and federal supervision and control of the state agencies employed to accomplish those purposes. The amount returned to a state in this category is less than the amount taken from it by the federal taxation and is equal to only the remainder of the federal taxes collected from the people of the state, after the federal government has deducted such amounts as it deems necessary to provide federal subsidies for other states. To the extent that the grant-in-aid payable to any state is less than the money collected from the people of the state by the federal government for the purpose of providing such federal subsidies in general, the ability of that state to provide for its own people is diminished.

If the distribution of federal grants-in-aid was made according to the actual necessities of the several states, as determined by a fair and open study of the situation, there could be little or no objection to them. No one would object to the making of grants of public money to relieve distress in any state that the state itself was financially unable to relieve, but the idea of making such grants even to the richest and most prosperous states in the Union is hardly compatible with the hypothesis on which the making of such grants is popularly believed to be based. Appropriations have been made by the federal government without criticism or complaint for the direct relief of suffering even in foreign countries, and certainly no criticism has been or will be voiced in making appropriations for such relief in this country. But when the federal government levies taxes on persons in states not in need, in excess of the requirements of the states that are in need, and then returns the excess thus collected to the state from which it was collected but only on condition that the state subject certain intrastate affairs to the supervision and control by some federal appointive officer, the entire plan savors strongly of an effort to concentrate power in Washington at the expense of the states.

Dr. Baker points out that the pending Wagner bill to amend the Social Security Act, if enacted, will make available to the people of Alabama a degree of medical, nursing and hospital care never known in the past. If there is actual need for a degree of medical, nursing and hospital care in Alabama that has never been known in the past, and if the state of Alabama is unable to provide it, by all means let it be provided. But even if such a need is shown in Alabama and in some other states, but not in all, that fact does not justify imposing on all states the system of federally subsidized and controlled relief that may be necessary in Alabama and other states similarly situated. Certainly some states are able to look after their own people, without federal grants-in-aid and federal supervision and control. It may be claimed, of course, that the federal government must deal with every state on an equal footing, although there is no such requirement in the constitution; but, as has already been pointed out, grants-in-aid such as are proposed by the Wagner bill do not operate uniformly on all states. They place all states equally under federal supervision and control, it is true, but they result in the taking of money from the people of some states for distribution among the people of other states, thus lessening the financial resources of the states from which the money was taken in the first instance for the benefit of other states. The plan seems to be devised for the redistribution of wealth among the states. How far it may go toward promoting a spirit of complaisant dependence among the states, no one can foretell.

Dr. Baker emphasizes the fact that—

> No system of health insurance is contemplated in the bill as a function of the federal government, nor is any participating state required to institute such a system. . . . The general program of medical care which a particular state may formulate as best for its own people may be limited, at the discretion of its officials, to persons on relief or, again at their discretion, it may be broadened to include those of nonrelief status. It may be financed entirely by insurance contributions, from tax funds or from both. . . .
>
> In addition to the health services in the preventive and curative fields already mentioned, the bill provides grants-in-aid to the states to be used in setting up insurance plans by means of which cash benefits may be made available during periods of temporary disability.

While Dr. Baker's statement concerning health insurance is strictly correct, it hardly gives a true picture of the purpose and effect of the bill so far as health insurance is concerned.

The bill authorizes appropriations for grants to states for medical care amounting to $35,000,000 and of $10,000,000 for temporary disability compensation for the fiscal year ending June 30, 1940, and for unlimited appropriations thereafter. To obtain grants from the appropriation for medical care, a state must have submitted to the Social Security Board state plans satisfactory to that board, extending and improving medical care. Nothing in the bill limits this proposed medical care to indigent persons or even to persons of moderate means. Nothing in the bill defines the particular type of medical service that is to be provided. The Social Security Board seems to be at liberty to refuse to approve any state system that does not meet its ideas of social economics. It may refuse to approve any proposed system unless it provides for the distribution of medical service by a salaried state staff. It may refuse to approve any system that does not provide for medical service with free choice of physicians, paid on a fee basis. On the other hand, it may refuse to approve any system that is not based on strictly insurance principles, even with state payroll taxes and the usual accompaniments of health insurance. Any such system may possibly be styled a "state" system, but in order to obtain the federal subsidy it must have the approval of federal officers and in last analysis such a system is a "federal" system or at most a "federal-state" system.

Dr. Baker's statement that the insurance plans proposed in the Wagner bill to provide temporary disability compensation for persons temporarily disabled by illness or injury provide for cash benefits is incomplete, for the bill expressly provides that the Social Security Board "shall not approve the plan of any State which does not have a plan or plans approved under this Act under which the Board finds that reasonably adequate medical services, including preventive services, are available to minimize disability among those covered under the State plan for temporary disability compensation." This necessarily implies the setting up by the state of a medical service of some kind to care for persons who are temporarily disabled and who are entitled to the benefits under the state plan. Nothing in the bill limits the beneficiaries of a state system of disability compensation to employed or even to employable persons. In fact, the bill expressly provides that disability, to be compensable, shall not have arisen out of or in the course of employment. Here certainly we have the germ of a full-fledged system of health insurance. When considered in connection with the provisions of the bill that authorize federal subsidies for state systems of medical care (which is defined to include all services and supplies necessary for the prevention, diagnosis and treatment of illness and disability) the provisions relating to disability compensation seem to leave the entire matter of health insurance throughout the entire United States to the judgment of the Social Security Board rather than to Congress, where it belongs.

Nothing in what is here written is intended in any way to reflect on the officers who are now charged with administering federal laws authorizing federal grants-in-aid, but officers come and officers go, and what an officer feels today with respect to governmental operations in the field of social economics and the administration of state aid is not necessarily what another officer will feel tomorrow. As a matter of fact, the people of the country have the right to have such matters determined by law and not by the mere judgment of individual federal executive officers.

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

LOUISIANA

In August 1936 a conference was held between representatives of the Louisiana State Medical Society and the Louisiana State Board of Health to outline a graduate program in obstetrics and pediatrics for physicians practicing throughout the state. It was proposed that the state society's committee on postgraduate education, which consists of five members with Dr. J. S. Kopfler as chairman, would act as the executive agency. On this committee is a member of the committee on maternal welfare and a member of the committee on medical education of the state medical society, together with the director of the Division of Maternal Child Health of the Louisiana State Board of Health. The professors of obstetrics in the two medical schools in the state outlined the educational program in obstetrics, and the professors in pediatrics actively participated in organizing the instruction in their special field. The expense of these courses was met with federal funds allocated to the state board of health.

Each course consists of five two hour sessions during one week. Teaching centers were selected in each of the eight councilor districts of the state. The district committee of from three to five physicians, including the district councilor, has charge of local arrangements and publicizes and assumes responsibility for the success of the graduate program in each district. Announcements are mailed to all physicians in the parishes of the district, and notices are published in the *New Orleans Medical and Surgical Journal*. The course as outlined includes lectures illustrated with movies, round table conferences, consultations on request and manikin demonstrations. Two in state lecturers are chosen for each locality by the state society's committee, one an obstetrician and one a pediatrician. Lecturers receive $25 a day, plus traveling expenses. Attendance records are kept by a member of the local committee. There is no registration fee.

From October to December 1936 instruction in obstetrics was given in nine towns. From twenty to forty physicians in each section attended. The auditorium of the city hall or the court house was used as a meeting place.

From December 1937 to December 1938 courses were given in obstetrics in ten towns and in pediatrics in fourteen towns in eighteen parishes of the state. Ten obstetricians and ten pediatricians have constituted the faculty. Two hundred and seventy-five physicians have attended the obstetric meetings and 407 have attended the sessions in pediatrics. Obstetric clinics have been held in six places where patients could be obtained for teaching. Six other parishes have selected pediatric courses, and it is planned that the state will be covered by the early part of 1939. All physicians of Louisiana have had an opportunity to avail themselves of this training. There are 1,324 members of the state medical society of the 2,200 physicians practicing in the state.

The Tulane University of Louisiana School of Medicine Department of Graduate Medical Studies was reorganized and its activities expanded in June 1937. All graduate medical education is now conducted under the supervision of the director of medical studies, Dr. H. W. Kostmayer. The faculty includes members of several departments of the school of medicine, and the facilities of the school are available to graduates who enroll

for study. The department has a budget, part of which provides instructors with compensation for the special intensive courses they give to graduates. Expenses of administration are charged against the graduate department's budget, but the use of the school's teaching facilities otherwise is not charged against this department.

The division of medical extension was created in 1937 and a full time assistant professor in the medical school was appointed as director. The medical extension division was organized for the purpose of conveying graduate instruction to those physicians who are unable to engage in formal study in medical centers. This division is supported largely by the Commonwealth Fund of New York, while Tulane University, the Mississippi State Medical Association and the Mississippi State Board of Health together provide approximately one fourth of the total budget. Fees from practicing physicians added an additional 5 per cent during the first year. Slightly more than half of the total expense during that year was allotted to administration and the remainder to instruction, including the travel expenses of instructors.

As now organized, the department of graduate medical studies offers several types of instruction to medical graduates: (1) a program for those who register in the graduate school of the university for advanced study in clinical divisions leading to advanced degrees after two or three years of residence; (2) fellowships in courses of study of one or more year's duration not leading to a degree—such courses are adaptable to the requirements of the specialty boards and may include instruction in the basic sciences; and (3) short, intensive courses in restricted fields such as cardiology, urology and dog and cadaver surgery. Applicants for these courses must have some preliminary training.

Intramural review courses designed for practicing physicians cover the general fields of medicine, surgery, gynecology and obstetrics. Instruction begins each January and continues for two periods of six weeks each, the second being a continuation of the lectures, clinics and demonstrations given in the first period. In these courses most of the morning instruction is given at the bedside of patients, although graduate students have no case responsibilities. The schedule provides for general review courses, one in medicine, one in surgery, including orthopedics and urology, one in gynecology and obstetrics and one in routine laboratory procedure. The latter includes clinical microscopy and requires about two hours each day. The fee for the first six weeks' course is $100 and for the succeeding six weeks $50. No diploma-like certificate is issued. Attendance averages from twenty-five to thirty physicians in medicine, from fifteen to twenty in surgery and from twelve to fourteen in gynecology and obstetrics.

An annual clinical conference of one week's duration is held each fall at the medical school, for which a fee of $5 is charged. One hundred and twenty-two registered last session. Other special review courses are available to medical graduates. The total registration for intramural courses in 1937-1938 was 212.

The activities of the division of medical extension in Mississippi have been reported previously.[1] The division acts as the organizing and disbursing agency in Mississippi's statewide program and cooperates with the medical, health and hospital organizations of the state. A course in syphilology and dermatology now in progress utilizes two instructors from the medical school. A six lecture course in minor surgery is to begin in January 1939 with four instructors from the medical school as speakers. Instruction is largely didactic, although clinical material is used whenever available.

A similar extension program in internal medicine starts in April 1939 in Alabama under the joint auspices of the Medical Association of the State of Alabama, the Alabama State Department of Health and the division of medical extension. Circuits of five towns are planned with the instructor visiting each teaching center one day a week for seven times. Approximately twenty or twenty-two centers will be established during the first year. A field organizer will precede the instructor and with the cooperation of the medical association's committee on postgraduate study will obtain the cooperation of local medical societies. A registration fee of $5 will be charged, but since the instructional expense will exceed the amount of this fee donations from the medical and health organizations in Alabama and the Commonwealth Fund of New York will be utilized.

The Graduate School of Medicine of Louisiana State University Medical Center was organized in 1936 when Dr. James T. Nix was appointed dean. The faculty and facilities of the medical center are at the disposal of the graduate school. Three types of intramural instruction have been offered: (1) general review courses designed for practicing physicians, (2) review courses in medicine and in the medical specialties and (3) review courses in surgery and the surgical specialties. In January and February 1938 eight such courses were offered for periods of from two to six weeks. A fee of $100 a month is charged nonresidents of the state for scheduled short review courses, while residents of Louisiana are charged one-half this amount. In addition, personal courses are arranged according to the needs of individual physicians.

Extramural instruction is being given throughout Louisiana in the form of seminars by groups of the faculty of the graduate school of medicine in cooperation with the general extension division of Louisiana State University. The first of these was held at the Lafayette Charity Hospital, Lafayette, La., Dec. 2 and 3, 1938. Twelve members of the faculty participated in the afternoon and evening meetings, which included a clinical pathologic conference. A registration fee of $1 was charged. More than 100 physicians attended. Similar programs designed for practicing physicians are projected in charity hospitals in three other towns of the state.

A special course in diagnosis, treatment and control of the venereal diseases was given at the medical center of Louisiana State University in cooperation with the United States Public Health Service, the Louisiana State Board of Health and the Department of Public Welfare of the City of New Orleans for a period of six weeks beginning Nov. 15, 1938. The attendance was limited to twelve physicians. Didactic instruction with clinical and laboratory experience, conferences and field studies was included.

The Louisiana State University Medical Library offers practicing physicians of the state a library service which includes the compilation of bibliographies. The only charge made is for postage on packages lent by the library.

The New Orleans Graduate Medical Assembly was organized in 1937 by a group of 150 physicians of the Orleans Parish Medical Society. These New Orleans physicians guaranteed the success of the four day assembly, which is held during February or March of each year. Lectures, dry clinics and round table discussions are conducted in a local hotel by eighteen out of state speakers. Louisiana physicians participate also, especially in the scientific exhibits. A registration fee of $10 is charged, while commercial exhibits aid in paying the travel expenses of speakers. Announcements are sent to physicians in thirteen Southern states and notices appear in state medical journals. In 1937, 632 physicians registered, 474 from Louisiana, with nineteen states and the District of Columbia being represented. In 1938, 610 physicians registered, 529 from Louisiana and the remainder from twenty other states.

A Feat of Giant Memory.—Diagnostic knowledge and ability is the first essential of good practice; it therefore becomes in teaching hospitals the most direct and universal measure of medical learning; it is the stepping-stone to personal success. Its highly competitive character is mainly responsible for the atmosphere of intenseness in these institutions. . . . But, from our present standpoint, it lends an exaggerated importance to knowledge of numerous rare diseases, of newly described phenomena of minor interest, and of newly described methods and tests. A desire for encyclopedic knowledge is fostered and grows; it moves in the direction of detail, for the phenomena studied are of great complexity and diversity, and present few of those connecting links in the form of principle or generalization that would serve to lighten what otherwise becomes a feat of giant memory. The result of this system is the loss of much that is of value in the earlier training.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 o'clock mountain time, 11 a. m. Pacific time).

Starting April 30, daylight saving time takes effect in Chicago. The program will therefore be broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there will be no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening, on and after May 1 (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

It has been necessary to curtail the length of the series by omitting the last two programs, which would have been broadcast June 14 and June 21. The series, therefore, will end with the broadcast scheduled for June 7.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

April 26. What Is a Doctor?
May 3. Healthier Mothers.
May 10. The Doctor's Workshop.

THE ST. LOUIS SESSION

Special Radio Programs

Radio programs have been arranged in connection with the annual session of the American Medical Association in St. Louis.

Dr. Irvin Abell, President of the Association, will broadcast over the Blue network of the National Broadcasting Company, Monday, May 15, from 4:15 to 4:30 p. m. central standard time. Dr. Rock Sleyster, President-Elect, will broadcast over the Columbia Broadcasting System, Monday, May 15, from 3:45 to 4 p. m.

Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association, will broadcast over the Blue network of the National Broadcasting Company Friday, May 19, from 4:15 to 4:30.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 1899 has passed the Senate, providing for the detail of a commissioned medical officer to serve as assistant to the Surgeon General of the United States Public Health Service. S. 1582 has passed the Senate, proposing to authorize the President to bestow a Meritorious Service Medal on any civil officer or employee of the United States, including commissioned officers of the Public Health Service, for the performance of an outstanding act or service involving great physical bravery or heroism, or for the performance of a service to the government or to humanity characterized by exceptional merit and involving a high degree of labor or effort above and beyond the ordinary and usual requirements of his office.

Bills Introduced.—S. 1744, introduced by Senator Reynolds, North Carolina, proposes to direct the Secretary of the Treasury to pay to Bernarr Macfadden the sum of $2,000 together with interest at the rate of 6 per cent per annum from Nov. 11, 1907, in full satisfaction of his claim against the United States for a refund of the fine paid by him as the result of his conviction on Oct. 22, 1907, in a United States district court for mailing certain issues of the magazine entitled *Physical Culture,* which contained "certain allegedly obscene matter." S. 1964, introduced by Senator Wagner, New York, proposes to authorize national banking associations to contribute to community funds or to charitable, philanthropic or benevolent instrumentalities conducive to public welfare such sums as its board of directors may deem expedient and in the interests of the association. H. R. 4923, introduced by Representative Geyer, California, proposes to provide for the forfeiture and seizure of matter sent through the mails relating to contraception, abortion or matter designed, adapted or intended for any indecent or immoral use. H. R. 5272, introduced by Representative Dunn, Pennsylvania, proposes to amend the Social Security Act so as to enable each state to adopt its own interpretation of the phrase "needy individuals who are blind" as used in the act. H. R. 5284, introduced by Representative Merritt, New York, proposes to authorize an appropriation of $1,875,000 to construct a 600 bed capacity veterans' hospital to accommodate general medical and surgical patients. H. R. 5379, introduced by Representative Smith, Ohio, proposes to amend the Federal Food, Drug and Cosmetic Act so as to relieve from certain of the labeling requirements of the act any "drug dispensed by a physician for the treatment of asthma and hay fever where such drug shall have been exclusively dispensed by physicians for at least ten years prior to June 25, 1939." S. 2093 and S. 2140, both introduced by Senator Bone, Washington, propose to permit federal income taxpayers to deduct in connection with their income taxes amounts not in excess of $250 paid during the taxable year for medical, dental, surgical or nursing treatment or hospitalization. H. R. 5134, introduced by Representative Dunn, Pennsylvania, proposes to amend the Social Security Act so as to authorize assistance to blind individuals whether or not the state plan extends only to those blind individuals whom the Social Security Board considers to be needy. H. R. 5475, introduced by Representative Gehrmann, Wisconsin, proposes to prohibit the importation of dairy products produced from milk or cream other than from cows either accredited free of bovine tuberculosis and Bang's disease or under test for such diseases. H. R. 5519, introduced by Representative Anderson, Missouri, proposes to confer certain benefits on commissioned officers and enlisted men in the Army, Navy, Marine Corps, Coast Guard, Geodetic Survey or Public Health Service of the United States who are placed on the retired list for physical disability incident to flying duty. H. R. 5577, introduced by Representative Izac, California, proposes to authorize an appropriation of $950,000 to construct and equip a marine hospital at San Diego. H. R. 5630, introduced by Representative Lea, California, proposes to amend the Federal Food, Drug and Cosmetic Act so as to postpone from June 25, 1939, to Jan. 1, 1940, the effective date of certain of its provisions that have not already gone into effect and of the regulations promulgated thereunder. The provisions of the act to be affected by the pending bill if it should be enacted relate for the most part to labeling requirements for foods, drugs, devices and cosmetics and the use of coal-tar dyes in foods, drugs and cosmetics. The bill also proposes to amend chapter V, section 502 (d) of the act so as to require the labels of drugs containing any narcotic or hypnotic substances to state only the "name and quantity or proportion" rather than the "name, quantity, and percentage" of such substances. H. R. 5657, introduced by Representative Sheppard, California, proposes to provide that any person who served in the military or naval forces of the United States during any war or during any recognized campaign or expedition, and who was not dishonorably separated from such service, shall be granted hos-

pitalization and domiciliary care by the Veterans' Administration, subject to the same restrictions and limitations as are now applicable to World War veterans. H. R. 5689, introduced by Representative Welch, California, proposes, among other things, to provide for the registry of surgeons as staff officers on vessels of the United States. H. R. 5736, introduced by Representative Voorhis, California, proposes to amend the Social Security Act so as to authorize an appropriation of $250,000,000 for the fiscal year ending June 30, 1940, and thereafter each year such sum as may be necessary to enable the states to grant assistance to needy persons who are not eligible for assistance under old-age, dependent children and aid to the blind provisions of the Social Security Act.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 2013, introduced by Senator Capper, Kansas, proposes to amend the Code of the District of Columbia to provide for the organization and regulation of cooperative associations. The bill provides, in part: "In the case of an association formed hereunder which arranges the rendering to its members, of licensed professional services on a nonprofit basis, said association shall not be subject to the insurance laws, shall not be construed as being in violation of any rule against corporate practice of professions, or in violation of statutes regulating licensure of professions." S. 2066, introduced by Senator Reynolds, North Carolina, proposes to provide for the use of scientific tests to determine the degree of intoxication of operators of motor vehicles in the District of Columbia whose vehicle causes personal injury or substantial damage to any other vehicle or property. H. R. 5673, introduced by Representative Bates, Kentucky, proposes to provide that the physicians assigned to Gallinger Municipal Hospital in the District of Columbia and known as chief resident physicians shall be designated and known as chief medical officers.

STATE MEDICAL LEGISLATION

Delaware

Bills Introduced.—Senate Substitute for S. 177, to amend the workmen's compensation act, proposes to increase to $300 from $150 the maximum liability of an employer for surgical, medical and hospital services which he must furnish an injured workman. Senate Substitute for S. 253 proposes to grant to physicians, nurses and hospitals treating persons injured through the negligence of others liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons by reason of their injuries.

Florida

Bills Introduced.—S. 35 proposes to require all applicants for licenses to practice the healing art, as a condition precedent to their examination or licensure by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, pathology and bacteriology, to be given by a board of examiners in the basic sciences, each of whose members must be learned in the basic sciences named and be a member of the faculty of a university or college in the state having a four year college course. S. 65 was reported favorably to the senate April 11, proposing to enact a new optometry practice act and to establish a state board of optometry to examine and license persons desiring to practice optometry. The bill proposes to define optometry as "the diagnosis of the human eye and its appendages, and the employment of any objective or subjective means or methods for the purpose of determining the refractive powers of the human eyes, or any visual, muscular, neurological or anatomic anomalies of the human eyes and their appendages, and the prescribing and employment of lenses, prisms, frames, mountings, orthoptic exercises, light frequencies and any other means for the correction, remedy or relief of any insufficiencies or abnormal conditions of the human eyes and their appendages." If the bill were enacted in its present form it might be unlawful for a licensed physician to perform any of the acts embraced in the above definition of optometry unless he were also licensed by the optometry board. S. 73 and H. 247 propose to prohibit the retail sale or distribution, except on the written prescription of a licensed physician, of amytal, luminal, veronal, barbital, acid diethylbarbituric or any trade marked or copyrighted preparation or compound registered in the United States Patent Office containing more than 4 grains to the avoirdupois or fluid ounce of these substances. H. 13 proposes to appropriate $10,000 annually to the State Board of Health for the purchase and distribution of insulin to residents suffering from diabetes or kindred diseases and who are financially unable to purchase the drug. H. 197 proposes to levy an annual state license tax of $10 on every person engaged in the practice of any profession. The bill further proposes to levy in addition a county license tax of $5. The bill also proposes to authorize incorporated cities and towns to impose such further license taxes as they deem proper provided the license tax so imposed does not exceed $5. H. 204 was favorably reported to the house April 12, proposing to authorize every licensed physician to compound and fill prescriptions written by him in his practice from a drug store or apothecary shop owned and operated by the physician.

Illinois

Bills Introduced.—H. 506 proposes that no person licensed under the medical practice act shall be permitted or compelled to testify without the consent of his patient, in any civil action, concerning any information acquired in attending the patient, which was necessary to enable him to prescribe or act for the patient. H. 612, to amend the medical practice act, proposes to limit licensure in the healing art to citizens of the United States. H. 616 proposes to authorize the issuance of a divorce if either spouse is incurably insane and has been so continuously for five years immediately preceding the filing of the complaint for divorce.

Maine

Bill Enacted.—H. 1433 was approved by the governor March 30, authorizing the formation of nonprofit hospital service corporations to enter into contracts with subscribers for the rendering of hospital service to them through hospitals contracting to do so with the corporations in question.

Bill Introduced.—H. 2230 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood and to submit that sample for a standard serologic test for syphilis to a laboratory of the state department of health and welfare or to a laboratory approved by the department.

Michigan

Bills Introduced.—S. 269 proposes to enact a separate naturopathic practice act and to establish a board of examiners in naturopathy to examine and license persons to practice naturopathy. The bill provides that "for the purpose of this act naturopathy is defined to include mechanotherapy, of every articulation of the human body but not to adjust any articular subluxation of the spinal column, corrective and orthopedic gymnastics, psychotherapy, hydrotherapy and mineral baths, electrotherapy, thermotherapy, phototherapy, chromotherapy, vibrotherapy, thalmotherapy, dietetics which shall consist of and include the use of foods and such biochemical tissue-building products and cell-salts, organic and inorganic, as are found in the normal body, and the use of vegetable oils and dehydrated and pulverized fruits, flowers, seeds, barks, roots, herbs and vegetables, uncompounded and in their natural state." The bill also proposes to make it unlawful for a licentiate to use any title other than the title "doctor of naturopathy." S. 317 proposes to regulate the manufacturing, producing, sale and distribution of drugs, cosmetics and medical supplies and to enact a new pharmacy practice act. S. 318, to amend the narcotic drug act, proposes, among other things, to permit a physician to cause narcotic drugs to be administered by a nurse or intern under his direction. The present law provides that he may cause such drugs to be administered by a nurse or intern under his direction *and supervision.* S. 319 proposes to regulate the manufacture, sale and advertising of foods, drugs, cosmetics and devices. H. 386 proposes to authorize the organization of corporations to operate voluntary nonprofit osteopathic care plans "whereby osteopathic care is provided at the expense of such corporation to such persons or groups of persons as shall become subscribers to such plan, under contracts which will entitle each such subscriber to definite health *and surgical care* and supplies, by licensed and registered doctors of the osteopathic school of medicine in their office, in

hospitals, and in the home." As noted, this bill proposes to permit osteopaths to render "surgical care." It is extremely doubtful whether the licenses granted osteopaths by virtue of the present osteopathic practice act permits such licentiates to practice surgery.

Minnesota

Bills Introduced.—S. 1262 proposes to prohibit the retail sale or distribution of devices, appliances, drugs or medicinal agents used for the prevention of venereal disease except by licensed physicians and persons licensed by the State Board of Pharmacy to do so. S. 1289 and H. 1454 propose a procedure whereby hospitals not operated for profit and registered with the State Department of Health may be reimbursed for care and treatment rendered indigents injured in motor vehicle accidents. H. 1367 and S. 1248 propose to authorize the organization of corporations to operate not for profit hospital service plans whereby hospital service may be provided by a hospital or hospitals, with whom such corporations have contracted, to those persons who become subscribers to such plans under contracts which entitle each subscriber to stated hospital care.

Missouri

Bills Introduced.—S. 348, to supplement the osteopathic practice act, proposes that in the administration of any public health project within the state, whether conducted with state funds or with funds furnished by the United States government to be expended by any Missouri agency, "all doctors of medicine and doctors of osteopathy must be accorded equal rights and privileges." H. 692 proposes as a condition precedent to the issuance of a license to marry that both parties to the proposed marriage present the certificate of a licensed physician that he or she is free from venereal disease in a communicable stage.

Nebraska

Bill Introduced.—Bill 507 proposes to authorize the organization of corporations not for profit to operate nonprofit hospital service plans whereby hospital service may be provided by such corporations or by hospitals with whom they have contracted to persons who become subscribers under contracts with the corporations. Hospital service to be provided by such a corporation is to consist of hospital care, including board and room, general nursing care, use of operating room, and routine laboratory services.

New Jersey

Bills Introduced.—S. 318 proposes that the law making it a misdemeanor to inflict unnecessary cruelty on a living animal shall not be construed to prohibit or interfere with properly conducted scientific experiments performed under the authority of the State Department of Health. The present law apparently limits the institutions or societies which the department may authorize to conduct such experiments by stating that the department may authorize such experiments to be conducted by agricultural stations and schools maintained by the state or federal government or by medical societies, universities, colleges and philanthropic institutions incorporated or authorized to do business in the state and having among their corporate purposes investigation into the causes, nature, prevention and cure of diseases. A. 296 proposes extensive amendments to the existing medical practice act. Among other things, the bill proposes to authorize the issuance of licenses to naturopaths and to provide that two members of the board of medical examiners must be naturopaths. The bill also proposes that persons licensed to practice osteopathy prior to May 23, 1935, may continue to practice osteopathy "as herein defined," defining the practice of osteopathy to "include the diagnosing, treating, operating or prescribing for any human disease, pain, injury, deformity, mental or physical condition; *provided, however,* that a license to practice osteopathy shall not permit the holder thereof to prescribe, administer or dispense drugs for internal use in the treatment of any human ailment, disease, pain, injury, deformity, mental or physical condition or to perform such surgical operations as require cutting." The bill also proposes to redefine the practice of chiropractic to "include the diagnosing, treating, dietary and hygienic control, and the detecting and adjusting, by hand of vertebral subluxations for the relief of pain and disease; *provided, however,* that a license to practice chiropractic shall not entitle the holder to perform surgery or administer drugs." The bill proposes also to require applicants for a license to practice any form of the healing art to present evidence, among other things, of having completed an internship acceptable to the board for at least one year in a hospital approved by the board or in lieu thereof to have completed one year of postgraduate work acceptable to the board except that naturopaths and chiropractors may serve internships in professional schools or clinics approved by members of the board of examiners who are osteopaths, chiropractors and naturopaths. A. 459 proposes to enact a separate chiropractic practice act and to establish a board of chiropractic examiners to examine and license persons to practice chiropractic. The bill proposes to define "chiropractic" as "The science of diagnosing, locating and correcting interference with nerve transmission and expression. The license to practice chiropractic shall include diagnosing, treating and prescribing for any human disease, pain, injury, deformity, mental or physical condition; provided, however, that a license to practice chiropractic shall not permit the holder thereof to prescribe, administer, or dispense drugs in the treatment of any human ailment, disease, pain, injury, deformity, mental or physical condition or to perform such surgical operations as require cutting."

New York

Bills Introduced.—A. 2251 and S. 1786 propose to require the state to reimburse a county 75 per cent of the total expended by it in extending "physical repair" to physically handicapped adult unemployed persons. The bills define "physical repair" as "the substantial correction or cure, by surgical or medical treatment and care, or by hospitalization, or by use of approved apparatus or device, of physical defects or physical disabilities of physically handicapped adult unemployed persons in such manner and to such extent as reasonably may be expected to fit them for remunerative occupation or employment." The bills then impose on the counties or other political subdivisions the duty of supplying such "physical repair" to the individuals noted. A. 2252 and A. 2241 propose a system of compulsory and voluntary health insurance, whose benefits are to consist of all forms of medical, dental and hospital services. All employees, excepting only persons employed at other than manual labor and receiving wages in excess of $2,500 a year, are to be subject to the compulsory insurance of the bill. All other persons are eligible to accept the voluntary insurance offered by them. S. 1776 and A. 2243 propose to create a temporary commission to survey the existence and prevalence of hay fever in the state, to devise ways and means for its prevention and elimination and to recommend methods for the treatment, relief and cure of persons suffering from hay fever. The bill proposes to appropriate $10,000 to defray the expense of the commission. A. 2242 proposes to prohibit the employment as a domestic servant of any person who does not possess a physician's certificate, executed after a physical examination and a standard serologic test for syphilis, that the person named is not infected with syphilis, or, if infected, is not in a stage of that disease whereby it may become communicable. In effect, the bill proposes to require such servants to submit to the examination stated annually. S. 1719 proposes to recodify the insurance laws of the state. It includes an article IX-C, which will permit the organization of nonprofit corporations either (1) to furnish medical expense indemnity or (2) to operate hospital service plans to persons who become subscribers under contracts with such corporations. Medical expense indemnity is to consist of reimbursement for medical care provided through duly licensed physicians, for nursing service and for furnishing necessary appliances, medicines and supplies. Each such plan must be open to the participation of duly licensed physicians without discrimination against schools of medical practice. S. 1627 and A. 2082 propose to extend to March 15, 1940, the life of the committee authorized by chapter 682, Laws, 1938, to investigate the health requirements of the people and to recommend such health insurance proposals or proposals with respect to state medicine as it deems advisable. A. 2107 proposes, in effect, to permit each recipient of relief to select the physician or dentist he desires to treat him at state expense.

Oklahoma

Bills Introduced.—H. 519, to amend the medical practice act, proposes (1) to require representation on the board of medical examiners for regular, eclectic and homeopathic physicians,

omitting the provision in the present law which requires one member of the board to be a physio-medic physician; (2) to provide that "the employment of what is commonly known as 'cappers' or 'steerers' in procuring practice" shall be cause for the revocation or suspension of a license "Provided that the term 'Cappers' or 'Steerers' shall not be construed to apply to: Bona fide Agents of Hospitals and Clinics legally organized. Provided further that such hospitals or clinics shall not be permitted to enter into contracts for hospital or medical services to be performed within thirty days of the date of said contract and provided further that said organization of clinics or hospitals shall be organized on a mutual or cooperative non-profit plan in connection with some recognized farm or labor union or church or charitable organization"; (3) to make it a ground for revocation or suspension of a license for a licentiate to have professional connection with or to lend his name to any person engaged unlawfully in the practice of medicine and surgery or for a licentiate to engage in practice under any name other than the one specified in his license; (4) to provide that a licentiate whose license has been revoked or suspended by the board of examiners may appeal to the district court of the county of his residence, which is to try the case de novo, the present law providing for an appeal directly to the Supreme Court from the decision of the board, and (5) to provide that no decision of the board revoking or suspending a license shall become final "pending final decision of the Supreme Court of this State." H. 624 proposes to repeal the present chiropractic practice act and apparently the basic science act so far as it relates to chiropractors. The bill proposes that the governor of the state, the secretary of state and the chairman of the corporation commission shall constitute a board of commissioners to determine the reputability of chiropractic educational institutions. A person desiring to practice chiropractic must apply to this board for a certificate of reputability of the chiropractic institution from which he graduated. On the issue of such a certificate, a person designated as a trustee to enforce the act is required to issue without examination or any other showing of qualifications a license to practice chiropractic. Apparently an applicant to obtain such a license need not pass a basic science examination. The bill proposes to define chiropractic as "the science and art of Chiropractic as taught in reputable Chiropractic Educational Institutions; provided that the art of Chiropractic consists in the palpation and adjusting of disrelationship in or of the vertebral column, and incidentally that of any part of the human body that in any manner affects the attitude or relationship of the vertebral column, by the hands of the Chiropractor only, to relieve or remove interference with the receipt, transmission, or application of nerve force."

Pennsylvania

Bills Introduced.—H. 671 proposes a system of compulsory and voluntary health insurance, the benefits of which are to consist, among other things, of all forms of medical, dental and hospital services. All employees except farm laborers and domestic servants of an employer having less than three domestic servants are to be subject to the compulsory features of the bill. All other persons may elect to come under the voluntary provisions of the bill. H. 685 and H. 686 propose to authorize the organization of corporations to operate nonprofit medical service plans whereby medical services may be provided to subscribers of low income "for prepayment, periodical or lump sum payments." H. 709 proposes to prohibit the manufacture, distribution or advertising of misbranded or adulterated foods, drugs, cosmetics and devices. H. 716 proposes to authorize any licensed optometrist to issue the certificate of ocular and visual efficiency which may be required by any law of the commonwealth or by any ordinance or resolution of any political subdivision of the commonwealth. H. 727 proposes (1) to prohibit the operation of a pharmacy or hospital unless registered with the State Board of Pharmacy and (2) to prohibit any person or broker, except a person owning or operating or employed in a pharmacy, hospital, place of manufacture or wholesale vender's place of business from vending any drugs, cosmetics or medical supplies unless licensed by the State Board of Pharmacy. H. 728 proposes to place the sale and distribution of cosmetics, as defined, within the prohibitions of the pharmacy practice act. H. 756 proposes to require the Department of Welfare to supply hearing aids or devices to persons who are deaf or hard of hearing and who are financially unable to purchase them. H. 934 proposes to authorize the formation of corporations "for the purpose of establishing, maintaining and operating a non-profit healing art service plan whereby healing arts services may be provided through any person registered with such corporation to subscribers thereto and their dependents." Healing art services, according to the bill, means the general and usual services rendered and care administered by doctors of medicine, doctors of osteopathy, dentists, registered nurses and registered pharmacists. The bill proposes that each branch of the healing arts noted which desires to participate in such a corporation shall have at least one incorporator and that no branch of the healing arts shall have a majority of incorporators. S. 318 proposes to authorize the sexual sterilization of inmates of state institutions who are criminally insane or who have been convicted a second time of a sex crime. H. 786 proposes to enact a separate chiropractic practice act and to establish an independent chiropractic board of examination and licensure to examine and license persons applying for licenses to practice chiropractic. The bill defines chiropractic as "the examination of the human spine by observation palpation or X-ray and the adjustment of any or all misalignments of vertebrae or adjacent bones or tissues through the use of the hands." H. 818 proposes to appropriate $10,000 to the Department of Health for the care and maintenance of carriers of typhoid fever bacilli.

Rhode Island

Bill Passed.—H. 782 passed the house March 29, proposing to grant to hospitals treating persons injured by reason of an accident not covered by the workmen's compensation act, liens on all claims, rights of action, judgments or compromises accruing to the injured persons because of their injuries.

Bill Introduced.—S. 181 proposes to require all applicants for licenses to practice any form of the healing art as a condition precedent to examination and licensure by their respective "professional" boards, to pass examinations in anatomy, physiology, pathology, symptomatology, chemistry, bacteriology and public health, to be given by the board of examiners in the basic sciences. The members of this board are to be selected because of their knowledge of the basic sciences mentioned and each member is to be a member of the faculty either of Brown University, of Rhode Island State College or of Providence College. No member of the board may be actually engaged in the practice of the healing art.

Texas

Bill Introduced.—H. 897 proposes to prohibit the sale of any truss or other mechanical device commonly used for the relief of rupture or hernia, except on the written prescription of a licensed physician. The bill also proposes to make it unlawful for any person other than a licensed physician to offer to fit any such truss or mechanical device.

Vermont

Bill Enacted.—H. 68 was approved by the governor April 10, authorizing the organization of corporations to operate nonprofit hospital service plans whereby hospital care may be provided by hospitals with whom such corporations have contracted for such care to such of the public as become subscribers to plans under contracts which entitle each subscriber to stated hospital care.

Wisconsin

Bills Introduced.—A. 543, to amend the medical practice act, proposes that no hospital supported in whole or in part by public funds or exempt from public taxation shall discriminate against any physician whose license to practice has been revoked and subsequently restored, nor deny him admission to practice in such hospital. A. 574 proposes to require the expenditure annually of $25,000 for the study of and research into the causes, prevention and cure of cancer. A. 599 proposes to require licensed physicians who are nonresidents to file their licenses or certificates with the county clerk in each county in which they practice.

WOMAN'S AUXILIARY

Georgia

At a meeting of the auxiliary to the Clark County Medical Society, Dr. W. D. Gholston, Danielsville, spoke on socialized medicine. Miss Susan Myrick, columnist and feature writer of the Macon *Telegraph*, spoke on "Problems of the Adolescent" at a recent meeting of the auxiliary to the Bibb County Medical Society.

The auxiliary to the Fulton County Medical Society met recently at the Academy of Medicine in Atlanta. Mrs. Warren A. Coleman, president of the auxiliary to the Medical Association of Georgia, and Dean Raimundo de Ovies of St. Phillip's Cathedral gave addresses. The auxiliary sponsored a health program January 11, attended by presidents and health chairmen of the Parent Teacher Association. A film, "Three Counties Against Syphilis," depicted the work of the mobile unit last summer. The auxiliary has raised funds for the treatment of patients with infantile paralysis.

The auxiliary to the Richmond County Medical Society met at the home of Mrs. Ralph Chaney, Augusta, in November. Miss Fannie B. Shaw, director of health education of the state department of public health, was the speaker.

Idaho

The auxiliary to the Boise Medical Society met at the home of Mrs. O. F. Swindell January 10. Mrs. Edith Davis spoke on problems arising in the home and school in the care of twins and triplets. The south side auxiliary met January 13 at Twin Falls. Mrs. A. A. Boston reviewed an article on the American Medical Association which was recently published in *Fortune* magazine.

The auxiliary to the North Idaho Medical Association met in Lewiston January 18. The auxiliary is preparing a history of the medical men who were pioneers of the region and a collection of old instruments and other equipment used by them.

The auxiliary to the Kootenai County Medical Association met at the home of Mrs. Alexander Barclay Jr. in Coeur d'Alene January 3. Mrs. R. T. Henson, president, asked members to cooperate with other auxiliaries in compiling data on the early physicians of Idaho. Garments for infants were made and will be distributed through the county health unit.

Illinois

An auxiliary to the DeWitt County Medical Society was recently organized with the assistance of Mrs. Charles C. Winning, chairman of organization of the auxiliary to the Illinois State Medical Society.

Dr. Harry Otten, Springfield, spoke on socialized medicine at a meeting of the auxiliary to the McLean County Medical Society January 10.

At a meeting of the auxiliary to the Sangamon County Medical Society in Springfield January 9 Mrs. S. R. Magill reviewed "The Stormy Petrel of Surgery," and February 13 Dr. G. Henry Mundt of Chicago spoke on socialized medicine.

Iowa

The sixth Annual Health Essay Contest, sponsored by the Iowa State Medical Society on "Good Health and How to Maintain It," closed March 15. Any high school student in Iowa was eligible to participate. The judges included a member of the state department of public instruction, of the state department of health and of the Iowa State Medical Society and two members of the auxiliary.

Kentucky

The auxiliary to the Hardin County Medical Society in Elizabethtown was addressed by Mrs. Walter Scott, who spoke on the antepartum and maternity work which the TVA is doing in conjunction with the public health service.

Mrs. Arthur T. McCormack entertained the auxiliary to the Jefferson County Medical Society at Louisville on the occasion of the birthday of the Woman's Auxiliary Section of the *Kentucky Medical Journal*.

The Auxiliary has established a benevolent fund for widows and orphans of former members of the Jefferson County Medical Society. At a party to raise money for this fund in November $119 was realized. On November 30, the auxiliary, cooperating with the Social Hygiene Association, sponsored a motion picture "Under Five Flags," raising $25 for the benefit of the sewing unit of the auxiliary. The Hospital Committee raised funds for the Children's Free Hospital at Christmas time, and also distributed gifts to patients in the City Hospital.

Minnesota

The auxiliary to the Olmsted-Houston-Fillmore-Dodge County Medical Society met at the Mayo Foundation House, Rochester, January 4. Edward H. Weld Jr. discussed health insurance plans being tried in various localities. Mrs. H. C. Habein, president, gave an illustrated talk on England.

Dr. George A. Earl and Mr. F. M. Brist addressed the board meeting of the auxiliary to the Minnesota State Medical Association in St. Paul February 1.

Nebraska

Mrs. Lucian Stark, former member of the state legislature of Nebraska, discussed lobbying and legislative procedure at a meeting of the board of directors of the auxiliary to the Nebraska State Medical Association in Lincoln, January 16.

Oklahoma

The auxiliary to the Pittsburg County Medical Society met in December and prepared Christmas baskets, also contributing cod liver oil to families in need of this remedy. January 13 a meeting was held in McAlester. Mrs. Walter Dell reviewed the "Life of Baron Lerry, French Military Surgeon."

The auxiliary to the Garfield County Medical Society is helping underprivileged children in Enid.

Dr. Ned R. Smith gave an address on socialized medicine in foreign countries at a meeting of the auxiliary to the Tulsa County Medical Society January 3.

The auxiliary to the Oklahoma City Medical Society, January 25, resumed their regular monthly sewing and scrap-book making for the Crippled Children's Hospital, with sixty-seven members present. A report on Medical Legislation was given by Mrs. George Garrison, president of the auxiliary to the Oklahoma State Medical Association.

Oregon

An auxiliary to the Josephine County Medical Society was organized at Grants Pass in October. An address was given by Dr. S. B. Osgood, secretary of the county society. The members will have as a definite project the distribution of *Hygeia*.

The auxiliary to the Coos-Curry Counties Medical Society was held at Bandon in November. Many of the members drove long distances to attend the meeting. A program was held on "Socialized Medicine and How the Auxiliary Can Combat It."

Dr. Charles E. Sears spoke on "What the Medical Society Can Do to Provide Better Medical Aid to the People," and Dr. R. L. Benson on "The National Health Conference" before the auxiliary to the Multnomah Medical Society.

The Oregon auxiliary will stress the study of socialized medicine in all its auxiliaries this year.

Pennsylvania

The auxiliary to the Allegheny County Medical Society met in Pittsburgh November 22. Plans were made for forming study groups for the discussion of socialized medicine. Dr. George R. Harris, secretary of the medical society, and Mr. Homer Saint Gaudens, director of the Department of Fine Arts of Carnegie Institute, were speakers.

The auxiliary to the Berks County Medical Society in Reading January 21 held a health conference. Mrs. Augustus S. Kech discussed socialized medicine and Dr. Harry B. Corrigan spoke on "Communicable Diseases and Their Prevention."

Mrs. Walter F. Donaldson, president of the auxiliary to the Medical Society of the State of Pennsylvania, was speaker at a recent meeting of the auxiliary to the Lehigh Medical Society.

The auxiliary entertained with a card party November 30 for the benefit of the Medical Benevolence Fund.

The auxiliary to the Chester County Medical Society met at Glen Mills School November 15. The program was arranged by Major H. R. Hickman, superintendent.

At a meeting of the auxiliary to the Northampton County Medical Society November 9 Mrs. Donaldson spoke briefly on the enlarged public relations program that the state medical society had planned for the auxiliaries, suggesting that the county auxiliary hold a health institute each year.

South Carolina

Dr. W. A. Hart discussed the new Maternal Health Center in Richland County before the auxiliary to the Columbia Medical Society in November.

Dr. John F. Rainey spoke on heart disease in December before the auxiliary to the Greenville Medical Society. Among the guests were Mrs. Charles P. Corn, president-elect of the auxiliary to the Southern Medical Association, and Mrs. C. C. Ariail, president of the auxiliary to the South Carolina Medical Association.

Mrs. C. C. Ariail addressed the auxiliary to the Spartanburg County Medical Society at a recent meeting on "The Doctor's Wife and the Educational Project to Be Sponsored by Each Auxiliary."

Wisconsin

The auxiliary to the Dane County Medical Society, Madison, January 11, voted to donate $10 to the Chinese Aid Council for nursing and medical supplies.

The auxiliary to the Medical Society of Milwaukee County gave a tea and musicale in honor of the new officers January 13. More than 100 members were present. Dr. Eben J. Carey, dean of Marquette University School of Medicine, discussed the national health program at a meeting of the auxiliary February 10.

MEDICAL ECONOMIC ABSTRACTS

CASH INSURANCE IN FRANCE

According to a report of the French delegate to the recent meeting of the International Medical Association, the existence of a partial cash indemnity provision in the French system has enabled it to pass through a recent crisis without resorting to that deterioration of quality of medical service and consequent deception of the patient that invariably characterize such crises in systems based on service benefits.

According to the report, which appears in the *Revue internationale de médecine professionnelle et sociale* (**11**:133 [Nov.] 1938), the fall in the value of the franc led to an increase in the income limits for the insured and compelled the physicians to raise their fees as measured in the falling franc. The French system of sickness insurance provides that the insured shall pay approximately 20 per cent of a legal reimbursement fee schedule. The physician may charge whatever fee he wishes, which is paid by the insured, who then looks to the insurance organization for reimbursement of 80 per cent of a fixed schedule.

In 1937 and 1938 the cost of living increased so rapidly in Paris that the physicians were compelled to increase their charges. Since the reimbursement schedule remained fixed, the burden on the insured became much heavier until they were required in many cases to pay 50 per cent of the cost. To meet this situation, which in other countries has been met by a forced reduction of the quality of the service, the insurance administration, which had already raised the salaries of its own administrators, was compelled by the Ministry to raise the schedule of reimbursement. In spite of this increase, the insured is still compelled to pay about one third of the costs.

The French representative explains that the French system at least permits some fairly rapid adjustments to monetary or economic changes without the long and usually hopeless conflicts between physicians and insurance societies which arise out of attempts to adjust the payment for medical service.

UNEMPLOYMENT AND HEALTH INSURANCE IN GREAT BRITAIN

While the benefits provided by unemployment insurance in Great Britain have been frequently changed to meet conditions, health insurance provisions remain inflexible. This puzzles the Bureau of Research and Statistics of the Social Security Board, which has just published a report on "Unemployment and Health Insurance in Great Britain, 1911-1937," in which this conclusion concerning alterations in the respective systems is repeated several times. A royal commission was similarly puzzled in 1926 and could only say that this condition "seems to us difficult to defend."

The Bureau of Research and Statistics and the royal commission compared only cash payments for unemployment in the two systems and both overlooked the existence of the same failure to alter terms in accordance with new conditions in the provision for medical treatment. This inflexibility in medical service works a far greater injustice and probably offers the real explanation of the failure of cash payments during illness to keep step with similar payments under unemployment insurance. All existing compulsory sickness insurance systems balance their books by failure of patients to evaluate the quality of medical service given; this makes it unnecessary to raise cash premiums as scientific progress increases the cost of providing benefits.

Flexibility in unemployment insurance is due primarily to the fact that premiums and benefits are both paid in cash, the value of which can be judged by the insured. The inflexibility in sickness insurance is maintained by reason of the fact that when cash premiums are changed into service benefits before they reach the insured the latter are unable to judge what they receive and do not realize that the books are balanced at the expense of their health.

BEWARE OF COLLECTION AGENCIES

The officers of a large midwestern collection agency which used an "account purchasing" contract were sentenced to serve three years for use of the mails to defraud. After some court delays these officers are now in custody and on the way to the penitentiary.

For years physicians have been warned by THE JOURNAL to beware of collection agencies, especially those using contracts. An account purchasing contract gives the appearance of being a finance plan by promising to pay the physician from 50 to 80 per cent of the face value of current accounts listed for collection. Actually the agency using such a contract is not obligated to liquidate any accounts but offers the account purchasing device as an inducement to obtain a list of delinquent accounts from the physician.

Once the physician has signed this type of contract, he finds that it contains all the provisions of the old collection contract, permitting the agency to have ownership of the accounts, power of attorney to settle the accounts in any manner which the company chooses, full commissions on accounts when the dissatisfied physician seeks to have them withdrawn, and perhaps a docket fee entitling the agency to 50 cents on each account listed. A special feature of the account purchasing contract permits the agency to retain 25 or 30 per cent of the aggregate amount of the accounts listed for collection. If $500 worth of accounts has been listed, the agency is entitled, under the 30 per cent contract, to $150 before the physician has to be paid anything.

With the precedent set by the aforementioned case, collection agencies which pretend to be finance companies and withhold an accounting of money collected from delinquent debtors are now recognized by postal authorities as "schemes to defraud." Agents or officers of the agency in question have organized at least five other collection agencies which use similar contracts. There are also many other independently organized agencies that use such "account purchasing" contracts. The post office inspectors are waiting for complaints.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 1643

CALIFORNIA

University News.—A short course for practicing physicians on 'Endocrinology and Related Metabolic Diseases" was given at the University of California Medical School, San Francisco, April 5-8. The medical school observed 'alumni day' March 22 as a part of the celebration commemorating the seventy-first charter anniversary of the University of California.

Epidemic Diarrhea of the Newborn.—Two outbreaks of epidemic diarrhea in the newborn were investigated during February, one in the southern part of the state and the other in northern California, according to the bulletin of the state board of health. Both outbreaks occurred in nurseries connected with institutions. Clinically, they were identical. Within from five to seven days after birth the infants became ill with diarrhea, dehydration, loss of weight and toxemia. Eleven cases occurred in one nursery and twenty-seven in the other. The exact cause of these outbreaks is unknown and all bacteriologic work undertaken up to March 18 had proved negative. Certain control measures have proved effective in preventing the spread of the epidemic.

COLORADO

Annual Spring Clinics.—The sixth annual spring clinics of the Pueblo County Medical Society will be presented April 28-29 at the Congress Hotel, Pueblo. The speakers will be:

- Dr. John B. Farley, Pueblo, Corpus Luteum and Its Role in Vomiting of Pregnancy
- Dr. Scott A. Gale, Pueblo, The Kidney in Pregnancy
- Dr. William T. H. Baker, Pueblo, Congenital Uterine Malformations
- Dr. Clinton K. Smith, Kansas City, Mo., Urinary Infections
- Dr. John D. Geissinger, Pueblo, Vomiting in Infancy
- Dr. Charles W. Streamer, Pueblo, A Resume of Some of the Newer Things in Medicine
- Dr. Lester L. Ward, Pueblo, Lesions of the Lung Excluding Pneumonia and Tuberculosis
- Dr. Osgoode S. Philpott, Denver, Current Ideas Regarding Etiology, Diagnosis and Treatment of Herpes Zoster
- Dr. Francis W. Cutts, Pueblo, Fatalistic Attitudes in Modern Medicine
- Dr. Samuel B. Potter, Pueblo, Relaxations of the Pelvic Floor: Causes
- Dr. J. Sims Norman, Pueblo, Early Orthopedic Treatment of Infantile Paralysis
- Dr. William Andrew Bunten, Cheyenne, Craniocerebral Injuries
- Dr. Kenneth M. Kelley Jr., Pueblo, Toxic Reactions Following the Use of Sedatives
- Dr. Royal H. Finney, Pueblo, Amebiasis
- Dr. Frank H. Zimmerman, Pueblo, Dementia Praecox
- Dr. Tate Miller, Dallas, Texas, Colitis

In the evening there will be a stag banquet at the Colorado State Hospital.

CONNECTICUT

The State of Health.—The general death rate in Connecticut was 9.7 per thousand population, the lowest on record, according to provisional figures. The births totaled 23,397 for the year, accounting for a rate of 13.1 per thousand population, the highest since 1933, when it was 13.2. The infant mortality rate was 36.3 per thousand living births. The maternal mortality rate was 2.9 per thousand living births from a total of sixty-seven maternal deaths.

DELAWARE

Society News.—A symposium on heart disease was presented before the New Castle County Medical Society, Wilmington, March 17 by members of the staff of the Woman's Medical College of Pennsylvania: Drs. Henry D. Jump, Robert G. Torrey, Jacob H. Vastine and William G. Leaman Jr. Dr. Joseph Stokes Jr., Philadelphia, discussed "Advances in the Study of Acute Infectious Diseases' before the society February 21. Dr. M. Edward Marten, Brooklyn, lectured at the Delaware Academy of Medicine March 28 on "Advantages of the State Medical Examiner in Contrast to the Present Coroner's Office."

DISTRICT OF COLUMBIA

Lectures by Professor Carlson.—Dr. Anton J. Carlson, professor of physiology, Department of Medicine, Division of Biological Sciences, University of Chicago, will address the Academy of Medicine, Washington, April 24 on "Science and the Common Life." He will address the Smith-Reed-Russell Society of George Washington University School of Medicine April 25 on "Notes on Medical Education and Medical and Public Health Services in Russia and China."

Portrait of Dr. William A. White.—A portrait of the late Dr. William A. White, former superintendent of St. Elizabeths Hospital, Washington, was presented to the hospital by the Rev. U. G. B. Pierce, president of the board of visitors, on behalf of Dr. White's friends and associates. It was accepted on behalf of the Department of the Interior by Secretary Harold L. Ickes, who paid tribute to Dr. White's contribution to the hospital and to American psychiatry and who emphasized the fact that the hospital "always had been administered by outstanding men who had been free from political interference." Dr. Winfred Overholser, superintendent, announced that Mrs. White had given to the hospital Dr. White's library relating to psychiatry and the broad field of medical sciences, it was formally accepted by Secretary Ickes.

IDAHO

New Director of Public Health.—Dr. Howard L. McMartin, Boise, formerly director of the division of maternal and child health and crippled children, state department of public welfare, has been appointed director of the division of public health of the department.

ILLINOIS

Tuberculosis Meeting.—The annual meeting of the Illinois Tuberculosis Association will be held at the Pere Marquette Hotel, Peoria, April 24-25. Among other speakers will be: Drs. Edward Kent Ellis, Murphysboro, "The Family Physician and the Tuberculosis Problem in Southern Illinois", William T. Holladay, Amboy, 'The Family Physician Views the Tuberculosis Problem", Loren L. Collins, La Salle, "The Sanatorium Aids the Family Physician," and Frederick M. F. Meixner, Peoria, "The Peoria Sanatorium District."

State Medical Meeting in Rockford.—The ninety-ninth annual meeting of the Illinois State Medical Society will be held at Rockford May 2-4 with headquarters at the Faust Hotel, under the presidency of Dr. Samuel E. Munson, Springfield. Dr. Leroy E. Parkins, Boston, will deliver the oration in medicine Tuesday afternoon on "Integration of Personality Factors in Health and Disease" and Dr. Hiram Winnett Orr, Lincoln, the oration in surgery Wednesday morning on "The Prevention and Cure of Local and General Infection in Compound Fractures and Other Open Wounds." Among the physicians on the program are:

- Dr. Isidor Harrison Tumpeer, Chicago, The Upper Respiratory Revenge of the Allergic Child
- Dr. Mitchell A. Spellberg, Chicago, Role of Ceviramic Acid in Various Clinical Conditions
- Dr. Karl A. Meyer, Chicago, Management of Local and Spreading Peritonitis Associated with Appendicitis
- Dr. Warren H. Cole, Chicago, Surgery of the Common Bile Duct
- Dr. Winston H. Tucker, Evanston, Rocky Mountain Spotted Fever in Illinois
- Dr. Howard A. Lindberg, Chicago, The Pneumonia Control Program in Illinois
- Dr. Pierre A. Steele, Decatur, Tularemia
- Dr. Lawrence M. Hilt, Grand Rapids, Mich., Some Pitfalls in Roentgenologic Diagnosis

The program includes symposiums on pneumonia and fractures, one session on endocrinology and Tuesday afternoon the following instruction courses:

- Dr. Jacob J. Potter, Rockford, Anatomy and Pathology of the Middle Ear Tract
- Drs. Thomas C. Galloway and Eustace J. Benjamin, Evanston, Acute Laryngeal Obstruction: Its Causes, Pathology and Treatment
- Dr. Thomas D. Allen, Chicago, Gonioscopy
- Dr. George P. Guibor, Ottawa, Ill., Concomitant Strabismus: Some Important Details in Its Diagnosis

The secretaries' conference will be held Tuesday evening with the following speakers:

- Dr. Robert S. Berghoff, Chicago, Cooperation of the County Secretaries with the Scientific Committee
- Dr. William W. Bauer, Chicago, The Influence of Health Education on the Practice of Medicine
- Dr. Herman M. Soloway, Chicago, Syphilis Control in Illinois: Its Relation to County Societies

Among others, Dr. Elston L. Belknap, Milwaukee, will address the Central States Society of Industrial Medicine and Surgery Tuesday morning on 'Practical Tests of Functional Capacity in Silicotics." At a meeting of the Physicians' Asso-

ciation, state department of public welfare Tuesday a feature will be a symposium on mental disorders following head trauma. The president's dinner will be Wednesday evening with Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect, American Medical Association, as the speaker. There will also be a veterans' service committee dinner and various alumni luncheons.

Chicago

Lectures at Billings Hospital.—Dr. August Krogh, director of the Institute of Zoophysiology, University of Copenhagen, Denmark, and winner of the 1920 Nobel Prize in physiology, will lecture at the Billings Hospital, University of Chicago, May 2. His subject will be "The Effects of Posture on Circulation." Dr. Thomas Addis, San Francisco, will lecture at the hospital April 24 on "The Treatment of Nephritis."

Surgical Prize Awarded to Dr. Hedin.—The first annual award of the Chicago Surgical Society will be made at a meeting of the society May 5 to Dr. Raymond F. Hedin of Cook County Hospital and the department of surgery, Rush Medical College. Dr. Hedin's essay, entitled "Polypoid Disease of the Colon: Two Proposed Surgical Procedures, Including the Description of a Colonoscope," will be presented at the same meeting. The $250 prize is offered to some young man devoting himself to surgery in Chicago, who is not a member of the Chicago Surgical Society, for meritorious work in one or both of the fields of experimental and clinical surgery.

Course on the Rorschach Method.—S. J. Beck, Ph.D., will conduct a course in the application of the Rorschach method at Michael Reese Hospital, Chicago, May 15-20, the week following the annual convention of the American Psychiatric Association. Additional information may be obtained from the librarian of the hospital. Tentative plans are also being made for a similar ten day course to be offered later in the summer. The dates will be arranged to meet the convenience of prospective registrants. Interested persons having preferences as to date are invited to communicate with the librarian of the hospital.

INDIANA

Changes in Health Officers.—Dr. William Harry Hutto has been appointed health officer of Kokomo and secretary of the city board of health, succeeding Dr. William J. Martin. Dr. Claude Dollens, Oolitic, has been appointed health officer of Lawrence County, succeeding the late Dr. John S. Woolery, Bedford. Dr. Thomas J. McKean, Montpellier, has been named health officer of Blackford County to succeed the late Dr. Elmer D. Shadday.

Society News.—Dr. Jacob Arnold Bargen, Rochester, Minn., discussed "Medical and Preoperative Management of Intestinal Obstruction" before the Tippecanoe County Medical Society at Lafayette April 11.——The LaPorte County Medical Society was addressed in Michigan City March 16 by Dr. Reed M. Nesbit, Ann Arbor, Mich., on "Treatment of Urinary Tract Infections with Reference to the Newer Drugs."——At a meeting of the Floyd County Medical Society, New Albany, March 10, Dr. John F. Habermel, New Albany, spoke on "Early Signs and Symptoms of Cancer."——Dr. Andrew M. Brenner, Winchester, addressed the Randolph County Medical Society in Winchester March 13 on "Electrocardiography and Its Practical Application."——At a meeting of the Madison County Medical Society, Anderson, recently Dr. Kenneth G. Kohlstaedt, Indianapolis, spoke on "Medical Treatment of Biliary Tract Diseases."——Dr. Raymond W. McNealy, Chicago, addressed the Muncie Academy of Medicine March 14 on "Vitamins in Surgery."

IOWA

Public Health Meeting.—The Iowa Public Health Association will hold its thirteenth annual meeting at the Hotel Savery, Des Moines, April 24. The following speakers will participate, among others:

Dr. Roy R. Jones, U. S. Public Health Service, Medical Aspects of Industrial Hygiene.
L. O. Nolf, Ph.D., Iowa City, Trichina Larvae in Rats: Relation to Trichiniasis (Trichinosis) in Man.
Dr. Florian E. Schmidt, Chicago, Present Status of Antipneumococcic Serum and Sulfapyridine in the Management of the Pneumonias.
Dr. Paul Stephen, Des Moines, Report of a Food-Borne Epidemic of Typhoid Fever.

State Medical Meeting in Des Moines.—The eighty-eighth annual session of the Iowa State Medical Society will be held at the Hotel Fort Des Moines, Des Moines, April 25-27 under the presidency of Dr. Arthur W. Erskine, Cedar Rapids, whose address will be entitled "Principles and Practice." Out-of-state speakers will include:

Dr. Soma Weiss, Boston, Treatment of Circulatory Collapse and Shock.
Dr. Nymphus Frederick Hicken, Omaha, Diagnosis of Breast Tumors with Management of Carcinoma.
Dr. Edwin A. Merritt, Washington, Hyperparathyroidism and Its Roentgen Treatment.
Dr. Frank H. Lahey, Boston, New Ideas in Thyroid Surgery.
Dr. William H. Holmes, Chicago, Bacillary Dysentery.
Col. Kent Nelson, Omaha, Medical Department of the United States Army in Civilian Conservation Corps Activities.
Dr. William L. Benedict, Rochester, Minn., The Etiology of Chorioretinitis.
Dr. Willis C. Campbell, Memphis, Tenn., Use of Vitallium for Fixation of Fractures.
Dr. Irvin Abell, Louisville, Ky., subject not announced.
Dr. Harold R. Conn, Akron, Ohio, Treatment of Fractures of the Spine.

Tuesday and Wednesday afternoons the program will be devoted to sectional conferences, including a symposium on the determination of alcohol in blood and urine. Thursday afternoon there will be a symposium on fractures. A smoker will be held Tuesday evening and the annual banquet Wednesday evening. The forty-second annual meeting of the State Society of Iowa Medical Women will be held April 25. Branch 19 of the American Medical Women's Association will also meet the twenty-fifth. The tenth annual session of the woman's auxiliary to the state medical society will be held April 25-26.

KENTUCKY

State Bureau of Medical Service Created.—At the request of the council of the Kentucky State Medical Association, a bureau of medical service has been created in the state department of health, with Dr. John B. Floyd, Richmond, as director. The bureau will assist the medical profession of the state in providing medical service for the indigent and the medically indigent. The director will be available for consultation with the profession in the formulation of plans, rules and regulations. The resolution submitted to the governor by the council of the state medical association stipulated that all plans provide for freedom of choice of physician, that there should be no restrictions on prescription or treatment except such as are necessary for protection of the public health and, further, that any expenditures made for the expansion of public health and maternal and child health services should not include treatment of disease except so far as this cannot be accomplished through private physicians. Dr. Floyd, a graduate of the University of Louisville School of Medicine in 1915, has been director of the bureau of tuberculosis of the state health department for two years. He formerly practiced in Richmond. He has served two terms in the state legislature. The council's request to the governor for the establishment of the bureau was made at the request of Drs. Irvin Abell, chairman of the committee on public relations; Arthur C. McCarty, chairman of the committee on medical economics, and Elmer L. Henderson, chairman of the committee on the study and provision of medical care of the state medical association, all of Louisville.

LOUISIANA

State Medical Meeting at Alexandria.—The sixtieth annual meeting of the Louisiana State Medical Society will be held at the Bentley Hotel, Alexandria, April 24-26, under the presidency of Dr. Joseph A. O'Hara, New Orleans. The guest speakers will include Judge William H. Byrnes Jr., New Orleans, who will deliver the annual oration; Dr. James C. Masson, Rochester, Minn., on "Carcinoma of the Uterus," and Dr. Sidney A. Portis, Chicago, "Hepatitis: Its Etiology, Diagnosis and Treatment." Among the Louisiana physicians on the program are:

Dr. Maurice Campagna, New Orleans, The Incidence of Peptic Ulcer in the Negro.
Dr. John Preston Davis, Lake Providence, Symptoms, Diagnosis and Treatment of Pellagra with Special Reference to the Use of Nicotinic Acid.
Drs. Dean H. Duncan, Shreveport, and Ernest N. Carmouche, Pineville, Metrazol Therapy in Psychotic Excitement.
Drs. Joseph R. Kriz and Herbert J. Schattenberg, New Orleans, Endometrial Changes and Their Relation to Ovarian Dysfunction.
Dr. Henson S. Coon, Monroe, Use of an Anatomicophysiologic Incision in Appendicitis.
Dr. Monte F. Meyer, New Orleans, Fractures of the Malar Bone with Eye, Ear, Nose and Throat Complications.
Drs. Joseph N. Ane and Leon J. Menville, New Orleans, Irradiation Therapy in Endocrine Dysfunction.

The past presidents' dinner will be held Monday evening April 24. Entertainment during the session will include golf and skeet. Other societies planning to meet at this time are the Louisiana Pediatric Society, Louisiana Gynecological and Obstetrical Society, Louisiana Urological Society, the Loui-

siana branch of the National Gastro-Enterology Society and the Louisiana Coroners' Association. There will also be a conference of eye, ear, nose and throat specialists.

MARYLAND

Monthly Meetings on Maternal Mortality.—The Baltimore City Medical Society has adopted a plan to hold monthly meetings to discuss the problems of maternal mortality, the first of which will be held April 27. The plan follows the suggestion of the maternal mortality committee and is akin to the study of maternal deaths in Baltimore which has been conducted for the past three years by a joint committee representing the Baltimore City Medical Society and the city health department. This survey will be continued two more years. In the monthly sessions devoted to this subject, the name of the patient, the name of the physician and the name of the hospital, if death occurred in a hospital, will not be made known. The meetings will be held on the fourth Thursday of each month and will be open to any physician practicing in Maryland.

MASSACHUSETTS

Annual Session of Psychiatry Society.—The New England Society of Psychiatry will hold its annual meeting at the Metropolitan State Hospital, Waltham, April 25. The speakers will include John W. Thompson, Ch.B., Boston, and Dr. William Corwin, Waltham, on schizophrenia.

Society News.—A symposium on the use of physical medicine in orthopedics will be presented before the New England Society of Physical Medicine, Boston, April 26 by Drs. Claude L. Payzant, Howard Moore and Gordon M. Morrison and Lucy G. Marshall, P.T. Dr. Abraham Myerson, Boston, discussed "Combined Physical Therapy and Motivation in the Treatment of the Psychoses" before the society March 15.

Extension Courses.—The Massachusetts Medical Society cooperating with the state department of public health, the U. S. Public Health Service and the U. S. Children's Bureau recently conducted the following extension courses:

Dr. Meinolph V. Kappius, March 5, Barnstable, Bleeding in the Third Trimester of Pregnancy.
Dr. Roy J. Heffernan, March 2, Bristol North, Operative Obstetrics.
Dr. Richard Cannon Eley, February 28, Bristol South, Whooping Cough: The Present Status of Vaccine Therapy Both as Prophylactic and Therapeutic Measure, the Early Diagnosis by Laboratory Procedures, and the Treatment of Complications.
Dr. Chester S. Keefer, March 2, Hampden, Anemia: Modern Methods in Diagnosis and Treatment of Blood Dyscrasias.
Dr. Laurence B. Ellis, February 28, Middlesex East, Bright's Disease and Hypertension: Evaluation of New Therapy: Diagnosis.
Dr. Howard B. Sprague, March 2, Middlesex North, Heart Disease: The Treatment of "Heart Attacks" or "Cardiovascular Emergencies."

The lecturers are all of Boston.

MINNESOTA

Postgraduate Courses.—The third annual series of postgraduate courses for physicians in obstetrics and pediatrics will begin April 26 to continue for five consecutive weeks in ten centers of the state, it is reported. Sponsored jointly by the Minnesota State Medical Association, the University of Minnesota Medical School and the state department of health, the course is financed by social security funds. The schedule of the courses is: April 26, Pine City and Winona; May 3, Fergus Falls and Little Falls; May 10, Willmar and Virginia; May 17, Worthington and Grand Rapids; May 24, Albert Lea and Crookston. There will be one full day meeting in each center, beginning at 8 a. m. and composed of eight lecture and discussion periods, four each on obstetrics and pediatrics.

NEW JERSEY

Society News.—Dr. Edgar Mayer, New York, addressed the Hudson County Medical Society April 4 on early diagnosis of tuberculosis.——Dr. Elliott C. Cutler, Boston, addressed the Academy of Medicine of Northern New Jersey, Newark, April 20 on "Postoperative Complications." Dr. Foster Kennedy, New York, will give a lecture at the academy April 27 entitled "A Critique on Present Trends in Medical Education" under the auspices of the academy's committee on public health and medical education and the health committee of the Newark Contemporary. Oscar Riddle, Ph.D., Cold Spring Harbor, N. Y., addressed a meeting of the academy March 16 on "Our Uncontrollable Governor—The Pituitary Gland."——Dr. William G. Leaman Jr., Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, April 14 on "The Prognosis in Heart Disease."

NEW YORK

Women's Medical Meeting.—The Women's Medical Society of New York State will hold its annual meeting in Syracuse April 23-24 under the presidency of Dr. Madge C. L. McGuinness, New York. Papers will be presented by Drs. Sophie Rabinoff, New York, on "Some Health Problems in a District Health Program"; Jane Sands Robb, Syracuse, "Prognostic Significance of the S-T Interval" and Helen G. Walker, Buffalo, "Newer Aspects in the Diagnosis and Treatment of Tuberculosis." Drs. Laura C. Harris, Syracuse, and Marguerite P. McCarthy, Solvay, will present case reports on "Influenzal Meningitis with Recovery" and "Erythroblastic Anemia" respectively. Sunday afternoon the society will give a reception in honor of Dr. William A. Groat, Syracuse, president of the Medical Society of the State of New York, other officers and delegates to the state society.

New York City

The Adam Miller Lecture.—Dr. George Hoyt Whipple, dean and professor of pathology, University of Rochester School of Medicine and Dentistry, delivered the third annual Adam Miller Lecture at Long Island College of Medicine April 6. His subject was "Experimental Anemia and the Building of Hemoglobin in the Body."

Medical Committees for the World's Fair.—Committees in charge of the medical and health exhibits at the New York World's Fair were recently announced. Dr. Livingston Farrand, Brewster, is chairman of the general committee and the following are among chairmen of the subcommittees for the exhibits in the Hall of Medical Science:

Dr. Arthur W. Booth, Elmira, N. Y., chairman of the Board of Trustees of the American Medical Association, exhibit on medical education sponsored by the Association.
Dr. Rufus I. Cole, Mount Kisco, N. Y., exhibit on pneumonia, Lederle Laboratories.
Dr. Kendall Emerson, tuberculosis, Queensboro Tuberculosis and Health Association.
Dr. Alfred E. Cohn, heart disease, Ciba Pharmaceutical Products, Inc.
Dr. Francis Carter Wood, cancer, New York City Cancer Committee.
Dr. William F. Snow, syphilis, Parke, Davis & Co.
Dr. James Ralph Scott, diabetes, Eli Lilly & Co.
Dr. Paul Reznikoff, blood diseases and anemia, Eli Lilly & Co.
Dr. Oswald T. Avery, local and general infections, American Museum of Health, Rockefeller Foundation and Rockefeller Institute for Medical Research.
Dr. Thomas M. Rivers, filtrable viruses, same sponsors as for local and general infections.
Dr. Frederick P. Gay, immunity, same sponsors as for local and general infections.
Dr. Paul M. Wood, anesthesia, Winthrop Chemical Company.

OHIO

State Medical Meeting at Toledo.—The ninety-third annual meeting of the Ohio State Medical Association will be held in Toledo May 3-4 at the Commodore Hotel under the presidency of Dr. Barney J. Hein, Toledo. There will be three general sessions and six section meetings. Part of Wednesday afternoon will be devoted to round table conferences. Guest speakers at the general sessions will be:

Dr. Anthony J. Lanza, New York, Silicosis—Present Status.
Dr. Herman O. Mosenthal, New York, Treatment of Nephritis.
Dr. Elliott C. Cutler, Boston, Preoperative and Postoperative Care.
Dr. Allen F. Voshell, Baltimore, Important Features in the Treatment of Fractures.
Bradley M. Patten, Ph.D., Ann Arbor, Mich., Microcinematographic and Electrocardiographic Study of the First Heart Beats and the Beginning of the Circulation in Living Embryos.
Dr. Elmer L. Sevringhaus, Madison, Wis., Pituitary Therapy.
Dr. William W. Herrick, New York, Medical Complications of Pregnancy and the Puerperium.

Dr. Francis Bruce Fralick, Ann Arbor, will address the section on eye, ear, nose and throat on "The Muscle Balance in Routine Refractions"; the program also includes the following Ohio physicians:

Dr. Harry Goldblatt, Cleveland, Experimental Observations on the Treatment of Hypertension.
Dr. George M. Curtis, Columbus, Lobectomy in the Treatment of Bronchiectasis.
Drs. Charles S. Higley and Harry Hauser, Cleveland, Diagnosis, Prognosis and Treatment of Hodgkin's Disease.
Dr. James R. Reeves, Columbus, The Value of Skin Tests as an Aid to Biologic Therapy in Rheumatoid Arthritis.
Dr. John W. Holloway, Cleveland, Regional Ileitis.
Dr. William H. Evans, Youngstown, Problems of Nutrition Encountered by the Ophthalmologist and the Otolaryngologist.
Dr. Theodore T. Zuck, Cleveland, The Application of Recent Knowledge to the Management of Controlled Conditions.
Dr. Newton W. Kaiser, Toledo, Alcoholic Psychoses.
Dr. James G. Kramer, Akron, The Present Status of Pertussis Immunization.

Gov. John W. Bricker will speak at the banquet Thursday evening May 4. Another feature will be a public health luncheon sponsored by the section on public health and pre-

ventive medicine Wednesday noon, at which the speakers will be Drs. Carl A. Wilzbach, health officer of Cincinnati, and Roll H. Markwith, Columbus, new state health officer. There will also be a hobby exhibit and the annual golf tournament at the Sylvania Country Club, Toledo, Tuesday May 2.

PENNSYLVANIA

Society News.—Dr. Karl Kornblum, Philadelphia, addressed the Delaware County Medical Society, Chester, April 13 on "Roentgen Examination of the Maternity Patient."——Dr. Wells P. Eagleton, Newark, N. J., addressed the Blair County Medical Society March 28 on medical economics.——Dr. Joseph H. Barach, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, April 6 on "Simplified Treatment of Diabetes."——Dr. Joseph C. Doane, Philadelphia, addressed the York County Medical Society, York, March 18 on "Alcoholism, Its Diagnosis and Treatment."——Dr. Henry T. Price, Pittsburgh, addressed the Harrisburg Academy of Medicine March 21 on "Meningitis in Children."——Dr. Aims C. McGuinness, Philadelphia, addressed the Dauphin County Medical Society, Harrisburg, March 7, on contagious diseases of childhood, with special reference to the uses of convalescent and immune human serums.

Philadelphia

Annual Campaign for Funds.—Philadelphia's annual campaign for funds, known as the "United Campaign" to finance 141 community agencies in welfare work is in progress for March and April. This year's goal is $4,000,000. It was stated that the fund was forced to cut its appropriations last year because insufficient money was collected.

Gifts to Woman's College.—The Woman's Medical College of Pennsylvania has received the following bequests in recent months: $25,000 from the late Dr. Jane Jenks Southern; $15,000 from the estate of Dr. Margaret P. Forcee-Kuyk, for endowment of the department of preventive medicine; $5,000 from the estate of Miss Maria Logan, Germantown; $7,500 from the estate of George Montgomery, New York, to establish a scholarship in the name of his deceased wife, Clara Babbitt Hyde Montgomery, and $20,000 from the estate of William E. Sellers for care of women and children in the college hospital.

Society News.—A symposium on prevention and early diagnosis of cancer was presented before the Philadelphia County Medical Society April 12 by Drs. Francis Ashley Faught, George E. Pfahler, John O. Bower, Louis H. Clerf, William Edward Chamberlain, Damon B. Pfeiffer and Catharine MacFarlane.——Speakers at a meeting of the Philadelphia Laryngological Society April 4 were Drs. Sol A. Goldberg on "Gangrene and Infection in Ear, Nose and Throat Complicating Diabetes Mellitus"; John B. Price, Norristown, Pa., "The Constitutional Background of Upper Respiratory Infections," and Myron A. Zacks, "Importance of Vestibular Findings Following Head Injuries."

Pittsburgh

Annual Meeting of County Society.—The Allegheny County Medical Society will hold its annual meeting May 2 at the William Penn Hotel with an afternoon scientific session followed by a banquet. The following speakers will appear on the scientific program:

Dr. Paul A. O'Leary, Rochester, Minn., Latent Syphilis and Wassermann-Fastness.
Dr. Walter E. Dandy, Baltimore, Diagnosis and Treatment of Lesions of the Cranial Nerves.
Dr. Wallace M. Yater, Washington, D. C., Heart Diseases Amenable to Surgery.
Dr. Harry E. Mock, Chicago, General and Special Rules in the Management of Skull Fractures.
Dr. Fred H. Albee, New York, Surgical Resection of Bone Sarcoma with Immediate Bone Graft Replacement.

Dr. Chauncey L. Palmer, president of the society, will preside, Hon. Cornelius D. Scully, mayor of the city, will make an address of welcome and Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will speak on "American Medicine and the National Government."

SOUTH CAROLINA

Society News.—Dr. Herman J. Moersch, Rochester, Minn., addressed the Columbia Medical Society March 13 on "Inflammatory Lesions of the Gastric and Duodenal Mucosa: Their Significance in Medical Practice." Dr. Richard B. Josey, Columbia, spoke on "Cardiac Complications of Nephritis in Children."——Dr. Edwards A. Park, Baltimore, addressed the Florence County Medical Society, Florence, February 23 on "Vitamin Deficiencies."

TENNESSEE

The Flexner Lectures at Vanderbilt.—Dr. Albert Szent-Györgi, director of the Institute for Medical Chemistry and professor of medical chemistry, Royal Hungarian Franz Joseph University, Szeged, Hungary, is the guest of Vanderbilt University School of Medicine, Nashville, for two months under the Abraham Flexner Lectureship. During March Dr. Szent-Györgi delivered lectures on general principles of biologic oxidation, respiration of muscle, fermentation and some problems of intermediary metabolism, vegetable respiration and vitamins in health and disease. He is spending April at the university as visiting professor of biochemistry. Dr. Szent-Györgi was the winner of the Nobel Prize in physiology and medicine for 1937. The Flexner Lectureship was established in 1927 by Mr. Bernard Flexner, a brother of Abraham Flexner.

TEXAS

New Health Officers.—Dr. Lee E. Edens recently succeeded Dr. Durwood L. Dodd as health officer of Austin.——Dr. John M. Hooper, Floydada, formerly of Pampa, has been appointed director of public health for district No. 1, which includes sixty counties in the Panhandle and South Plains area.——Dr. Francis T. Isbell, Eastland, has been appointed health officer of Eastland County and Dr. Frank B. Boyle, Big Springs, of Howard County.

VIRGINIA

McGuire Lectures and Postgraduate Clinics.—Dr. Wilder G. Penfield, director of the Neurological Institute, McGill University Faculty of Medicine, Montreal, Canada, will give the McGuire Lectures at the Medical College of Virginia, Richmond, April 27-28 on "Epilepsy, Mechanism and Pathology" and "Epilepsies—Selective Study and Surgical Therapy." A postgraduate seminar on neuropsychiatry will be held on the morning of April 28 with the following speakers: Drs. Hugh C. Henry, Richmond, director of state hospitals and associate in psychiatry at the school; James Asa Shield, associate in psychiatry; Joseph R. Blalock, Marion, associate in psychiatry; Robert Finley Gayle Jr., professor of neuropsychiatry, and George B. Arnold, superintendent of the Capitol State Colony for Feebleminded and Epileptics, Colony. In the afternoon there will be discussions and demonstrations with the following participants: Drs. Charles Bagley Jr., Baltimore; John M. Meredith, Charlottesville; Claude C. Coleman and William Gayle Crutchfield, Richmond. The lectures will be at the Richmond Academy of Medicine.

WISCONSIN

William Snow Miller Lecture.—Dr. Ko Kuei Chen, professor of pharmacology, Indiana University School of Medicine, and director of pharmacologic research, Lilly Research Laboratories, Indianapolis, delivered the twelfth annual William Snow Miller Lecture at the University of Wisconsin Medical School, Madison, April 6. His subject was "Cyanide Poisoning and Its Treatment."

Society News.—Dr. Loyal Davis, professor of surgery, Northwestern University Medical School, Chicago, gave an address at the University of Wisconsin Medical School, Madison, March 11 under the auspices of Alpha Omega Alpha, on "Experimental and Clinical Experiences in the Surgical Treatment of Hypertension."——Dr. William J. Dieckmann, Chicago, addressed the Rock County Medical Society, Beloit, recently on "Toxemias of Pregnancy."——Dr. Walter G. Sexton, Marshfield, addressed the Winnebago County Medical Society, Oshkosh, March 2 on "Renal Stones."——Dr. Friedrich Eigenberger, Sheboygan, addressed the Sheboygan County Medical Society, Sheboygan, February 28 on "New Laboratory Methods in Diagnosis of Cancer." Dr. Dexter H. Witte, Milwaukee, addressed the Sheboygan Woman's Club February 21 at the request of the county medical society on "Medical Care."

WYOMING

District Meeting.—The third annual meeting of the Central District Medical Society was held at Casper April 15-16 with the following speakers:

Dr. Ralph M. Stuck, Denver, Surgical Treatment of Epilepsy.
Dr. John Harry Murphy, Omaha, Sulfanilamide, Its Use in Infectious Diseases of Children.
Dr. Atha Thomas, Denver, Treatment of Fractures of the Elbow in Children.
Dr. William W. Wasson, Denver, Diseases of the Lungs.
Dr. Paul J. Connor, Denver, Diseases of the Thyroid Gland in Relation to Endocrinology.
Dr. Clarence B. Ingraham, Denver, Difficult Labors.

GENERAL

The Kober Lecture.—Col. Joseph F. Siler, director of the Army Medical School, delivered the annual Kober Lecture at Georgetown University Medical School, Washington, D. C., March 28, on a new vaccine for typhoid developed by the army. Colonel Siler was presented with a check for $500, provided under the terms of the Kober Foundation. The speaker for this annual lecture is selected in alternating years by the Medical Society of the District of Columbia, the Association of American Physicians and the Association of Military Surgeons.

Society News.—At the recent annual business meeting of the American Heart Association in New York, the following officers were elected to serve two years: Drs. William D. Stroud, Philadelphia, president; Paul D. White, Boston, vice president, and Howard B. Sprague, Boston, secretary.——The twenty-fourth annual meeting of the National Recreation Association will be held in Boston October 9-13.——The annual meeting of the Associated State Committees on Postgraduate Medical Education will be held at the Hotel De Soto, St. Louis, May 17, at 12:30 p. m.

Foundation Invites Applications for Grants.—The Dazian Foundation for Medical Research, recently established in accordance with the will of the late Henry Dazian, New York (THE JOURNAL, January 21, page 251), is prepared to award fellowships to graduates in medicine for graduate study and research and grants to laboratories, hospitals and similar institutions for research in medicine. Applications and inquiries should be addressed to the Secretary, 180 East Sixty-Fourth Street, New York. The board of directors of the foundation is as follows: Drs. Emanuel Libman, New York, president; Israel Strauss, New York, vice president; Philip Finkle, New York, secretary; Harrison S. Martland, Newark, N. J.; Mr. Emil Friedlander, assistant secretary and treasurer; Mr. William W. Cohen, treasurer, Mr. Alfred L. Rose and Mr. Harold Williams.

Dr. Jelliffe Honored.—The April issue of the *Journal of Nervous and Mental Diseases* is a special anniversary issue commemorating the thirty-fifth year of editorship of Dr. Smith Ely Jelliffe. Commemoration exercises and a dinner were held at the New York Academy of Medicine, April 22. The issue contains reviews of the different phases of Doctor Jelliffe's work, as well as scientific articles. The contributors are Drs. Adolf Meyer, Baltimore, Frederick Tilney, George Draper, New York, Earl D. Bond, Philadelphia, Oskar Diethelm, New York, Abraham A. Brill, New York, Karl A. Menninger, Topeka, Kan., Henry A. Riley, New York, Richard H. Hutchings, Utica, N. Y., and Louis Casamajor, New York. The committee of organization of the ceremonies comprised Doctors Brill, Menninger and Riley, and Drs. Iago Galdston, New York, Bernard Glueck, New York, Benjamin Karpman, Washington, D. C., and Gregory Stragnell, Bloomfield, N. J. The concluding article is entitled "The Editor Himself and His Adopted Child." This is followed by Doctor Jelliffe's bibliography, compiled year by year since 1890 making a total of 411 references.

Survey Office to Be Moved.—Headquarters of the Mental Hygiene Survey Committee, supported by a group of organizations, will be moved July 1 from New York to the U. S. Public Health Service headquarters in Washington in order that the committee's work may be coordinated with that of the mental hygiene division of the service. Offices of the survey committee have been in connection with the National Committee for Mental Hygiene and the work has been carried on with funds provided by the Rockefeller Foundation, the American Psychiatric Association and the public health service. Dr. Samuel W. Hamilton is medical director and Dr. Grover A. Kempf of the public health service is associate medical director of the committee, which was formed in 1936 to survey as many as possible of the 336 mental hospitals in the United States and Canada, to promote research and to encourage wider distribution of teaching facilities. One hundred and sixty-nine institutions in forty states have already been surveyed. Organizations represented on the committee are the American Psychiatric Association, the American Neurological Association, the American Medical Association, the American Board of Psychiatry and Neurology, the National Committee for Mental Hygiene, the U. S. Public Health Service and the Canadian Medical Association.

Societies for Experimental Biology.—The annual meeting of the Federation of American Societies for Experimental Biology will be held at the Royal York Hotel, Toronto, Canada, April 26-29. The federation represents the American Physiological Society, the American Society of Biological Chemists, Inc., the American Society for Pharmacology and Experimental Therapeutics, Inc., and the American Society for Experimental Pathology. A joint session will be held Thursday morning with the following speakers:

Dr. Eugene M. K. Geiling, Chicago, The Comparative Pharmacology of the Pituitary.
Dr. Maurice S. Jacobs, Philadelphia, Hemolysis, Cell Permeability and Cell Specificity.
Albert Baird Hastings, Ph.D., Boston, Recent Observations on Electrolyte Distribution in Tissues and Body Fluids.
Dr. Thomas M. Rivers, New York, The Nature of Filtrable Viruses.

The physiologists will discuss, among other things, the nervous system, the heart and the circulation, endocrines and metabolism, the digestive secretions, sex hormones, insulin, vitamins and absorption, pituitary, thyroid and thymus, gastrointestinal motility and the liver and the pancreas.

Morton A. Rubin, Ph.D., and Dr. Harry Freeman, Worcester, Mass., Brain Potential Changes During Cyclopropane Anesthesia.
Dr. Kenton R. Phelps, Cleveland, A New Method for the Gradual Occlusion of Coronary Arteries.
Dr. Reginald A. Shipley, Cleveland, The Effect of Anterior Pituitary Injections on the Blood Acetone Bodies of Adrenalectomized Rats.
Dr. Hance F. Haney and Willard C. Roley, B.S., Portland, Ore., Effect of Bile on the Secretion of the Small Intestine.

A joint symposium on chemotherapy will be held by the biochemists and pharmacologists with the following speakers:

Michael Heidelberger, Ph.D., New York, The Scientific Background of the Use of Rabbit Antibody in Pneumonia.
Dr. Eli K. Marshall Jr., Baltimore, Bacterial Chemotherapy with Sulfanilamide-Type Compounds.
George W. Raiziss, Ph.D., Philadelphia, Antipneumococcic Effect of Sulfapyridine and Related Compounds in Mice.
Leonard H. Cretcher, Ph.D., Pittsburgh, Structure and Antipneumococcic Activity in the Cinchona Series.

Among the pharmacologists on the program are:

H. J. White, Baltimore, Relationship Between Temperature and the Streptococcidal Activity of Sulfanilamide and Sulfapyridine in Vitro.
Charles R. Linegar, Ph.D., Washington, D. C., Effect of Ergotamine on the Hemodynamic Actions of Acetylcholine.
Frank W. Maurer, Ph.D., Washington, D. C., Further Studies of the Ganglionic and Peripheral Actions of Physostigmine.
Dr. Albert G. Young and Frederick F. Yonkman, Ph.D., Boston, *Ethyl Yohimbine in Experimental Hypertension.*

Included in the many papers on pathology will be:

Drs. Owen H. Wangensteen and Clarence Dennis, Minneapolis, Experimental Proof of the Obstructive Origin of Appendicitis in Man.
Dr. Marian W. Ropes, Dr. Walter Bauer and William V. B. Robertson, Boston, *Enzymatic Hydrolysis of Mucins by a Bacterial Enzyme and by Vitamin C.*
Louis D. Greenberg, Ph.D., and Dr. James F. Rinehart, San Francisco, The Stability of Ascorbic Acid in Blood.
Dr. Granville A. Bennett and Morris F. Shaffer, Ph.D., Boston, The Passage of Type III Pneumococci from the Blood Stream into the Joints and Certain Other Body Cavities of the Rabbit.

The pathology section will hold a joint symposium with the immunologists Thursday. Friday there will be a symposium on the chemistry and physiology of red blood cells and on the chemical reactions of vitamins in vivo. The pharmacologic society will conduct a symposium Friday on the mechanics of respiration. Other symposiums include those on proteins, the synapse and carbohydrate metabolism. The annual dinner will be Friday evening.

Government Services

New Veterans' Hospital

President Roosevelt approved a site at Marion, Ill., April 11 for construction of a $1,400,000 veterans' hospital to serve downstate Illinois, southern Indiana and western Kentucky, it was reported. The new hospital will have accommodations for 500 veterans, including 350 domiciliary patients and 150 receiving hospitalization treatment.

White House Conference on Children

A White House Conference on Children in a Democracy is being organized with President Roosevelt as honorary chairman, Secretary of Labor Frances Perkins as chairman and Miss Katherine F. Lenroot, chief of the Children's Bureau, U. S. Department of Labor, as secretary. The first session will be held at the White House April 26 and the last early in 1940, according to an announcement. Among physicians on the planning committee are Drs. Fred L. Adair, Chicago; Clifford G. Grulee, Evanston, Ill.; Henry F. Helmholz, Rochester, Minn.; Felix J. Underwood, Jackson, Miss.; Midian O. Bousfield, Chicago, and James S. Plant, Newark, N. J.

X-Ray Examination in Acute Diseases of Respiratory Tract

At the section of radiology of the Royal Society of Medicine, Dr. Peter Kerley opened a discussion on x-ray examination in acute diseases of the respiratory tract. A portable apparatus was generally necessary. Fine detail was rarely required and speed was important. A working distance of from 2½ to 3 feet was ample. His usual procedure was to let the patient lie back against the screen in the sitting posture. When the shadow of a consolidated base merged with that of the diaphragm or when the respiratory rate was too high or the patient too young or too ill to cooperate, a screen examination might be decisive. As to films, his advice was to take plenty and to overexpose or overpenetrate, since the presence of fluid and consolidation might then be differentiated. A lateral view should always be taken.

The best recognized though not the commonest acute disease of the respiratory tract in childhood was miliary tuberculosis. In infants under 9 months old the usual appearance was a large caseating area of pneumonia in one lung with round foci all over both lung fields; in older children and adults there was a widespread infiltration of millet seed size or larger shadows but seldom a pneumonic area. The significance of the size of the lesions was not clearly established, but he did not believe that the finer and more discrete the lesions the better the prognosis, as had been stated by some authorities.

In pneumonia infants tended to show localization to the paravertebral sulci and older children a more diffuse type of shadow. The dominant feature in infants was a dense homogeneous opacity with an outer border running parallel to the mediastinum from apex to base. The homogeneity of the shadow, the sharp outer border and the distribution transgressed the lobar divisions of the lung and indicated a mediastinal effusion, which appeared to be a frequent complication of paravertebral pneumonia in young children. Between the ages of 2 and 10 years two types of bronchopneumonia could be recognized. In one the foci were large and ill defined and might coalesce but did not extend into the root of the lung, as in lobar consolidation; in the other the foci were sometimes described as miliary bronchopneumonia and appeared to be common after measles. The complications of bronchopneumonia and lobar pneumonia in children were collapse and the presence of fluid. The former could be detected by the low position of the interlobar fissure, the opacity of the lobe and the displacement of the mediastinum to the diseased side. Fluid could be localized, but the roentgenogram did not show whether it was purulent or not. In young children mediastinal effusions were frequent, while in older children the ordinary axillary type was commoner. Empyemas occurred in odd situations and might be overlooked, and sometimes pseudocavities due to acute vesicular emphysema occurred both with lobar pneumonia and with bronchopneumonia in children. All these conditions were difficult even for a skilled radiologist to interpret, and roentgenograms taken by a layman and interpreted by a general practitioner might lead to disastrous results. Ring shadows or pseudocavities in the roentgenograms in cases of lobar pneumonia had been described by American writers and regarded as areas of aseptic necrosis. Rabin regarded them as due to arteritis with thrombosis and infarction. They were a purely radiologic discovery and had never been confirmed post mortem. They might be due to delayed resolution following collapse of a large segment or lobe. Emphysema was a natural reaction to collapse, and there was no reason why overdistended lobules should not contain fluid levels. In cases of influenzal bronchopneumonia the appearances suggested an area of intense hyperemia with pea-sized foci of consolidation not tending to coalesce.

Increase in Alcoholism

An article by Dr. G. Lavallée of Paris, which appears in the March 11 *Concours médical*, is entitled "France, the Country of Alcoholism." During the World War some vigorous measures were taken by the government to suppress the sale of absinth and to limit the number of saloons. Although the manufacture of absinth is prohibited, 2,000 new saloons were licensed in 1933. Two years later, distillers of 96 per cent alcohol were given privileges in the way of reduced taxes. This was followed by a rapid increase in the total quantity distilled, so that the population is drinking more and more beverages containing as high as 50 per cent alcohol. The Académie de médecine passed resolutions in 1936 calling the attention of the government to the dangers incident to the increase in drinking and especially to the number of workers who, instead of being benefited by a reduction in the number of working hours to forty a week, were spending their leisure time in saloons. Professor Née of Rouen, in a French department where drinks containing even more than 50 per cent alcohol are commonly taken, stated that at the Hôtel Dieu of that city 220 cases of delirium tremens had been treated from 1935 to 1937 with a mortality of 56 per cent. Many of these patients were not employed and received a daily allowance from the government, most of which was spent in saloons. The Rouen Medical Society at a recent meeting urged the government to take steps immediately to cut down the number of saloons, regulate the manufacture of alcoholic drinks and close the saloons during certain hours as in England and Germany. The production of alcohol has increased from 940,000 hectoliters in 1850 to 4,772,110 in 1935. During the same period, importation of alcohol rose from 5,555 to 692,376 hectoliters. In 1914 only 1,415,000 hectoliters of alcohol in some form was drunk, as compared to 6,149,571 hectoliters in 1935. The net income of the largest two firms engaged in making alcoholic beverages in France has increased 63 per cent and 53 per cent in 1936 as compared to 1935.

Tetanus and Tetaniform Syndromes

The report of cases of tetanus following laparotomy or as a complication of the puerperium often raises the question both as to the atrium of infection and whether the clinical picture corresponded in every detail to that which it is customary to associate with an infection by the tetanus bacillus. This question was raised by Dr. Pierre Lombard, who read a paper at the January 31 meeting of the Académie de médecine. He stated that patients are admitted to hospitals whose clinical symptoms correspond in every detail to the classic picture of tetanus and yet who show no wound to explain the entrance of the toxin into the body. According to Dr. Lombard there are a number of tetaniform states which cannot be differentiated from tetanus of infectious origin. If a wound is present as a potential atrium, inoculation of some of the excised tissue into guinea pigs is a far more certain method of finding the tetanus bacillus than cultures. The author reported six cases of children in whom the clinical picture was typical for tetanus and yet animal inoculations were negative. In five of the children only a small superficial abrasion of the skin of some portion of the lower extremity could be found. In the sixth no skin abrasion or other evidence of recent or older injury

could be found. The patient, a boy aged 9 years, complained of a severe pain in the back, which had begun suddenly and subsided as rapidly. Four days later, recurrence of the pain in the back was accompanied by abdominal pain and rigidity of the arms and legs. Two days subsequent to another attack, the child was sent to the hospital with a diagnosis of tetanus. Every five minutes, typical tetanic contractures of the muscles of the lower extremities and abdomen with marked opisthotonos were observed. These attacks did not cease in frequency until large doses of parathyroid extract were given. About three weeks after admission to the hospital there was complete cessation of the tetaniform syndrome.

Primary Tuberculous Infection Reproduced in Monkeys

An important contribution to the method in which children are primarily infected by the tubercle bacillus was reported at the February 14 meeting of the Académie de médecine by Prof. Jean Troisier and Miss Sifferlen. In preliminary experiments they found that when a drop of a culture of tubercle bacilli was instilled into the nose of mice previously anesthetized with ether the acid fast bacilli could be found within three minutes in the pulmonary alveoli. Two minutes later, some of these bacilli were found within the alveolar monocytes even before any phagocytes were visible. For a second series of experiments, monkeys were employed. In animals infected by this method, pathologic changes were found at the end of from one to two months which corresponded in every detail to those observed in primary tuberculous infection of infants. In the lungs, the changes are in general found in the middle and inferior lobe on the side where the bacilli were instilled into the nose. The pulmonary lesions are the size of a pea but are accompanied by a caseous involvement of the tracheobronchial lymph nodes. Although no macroscopic signs of involvement of other viscera exists, their inoculation into guinea pigs shows that the tuberculous infection is a generalized one. These experiments were undertaken with the object of proving that infants in contact with tuberculous individuals can during sleep be infected through inhaling air containing tubercle bacilli.

Graduate Courses in English at Paris Hospitals

The faculty of the medical school of the University of Paris in collaboration with the Association des relations médicales and American Medical Society of Paris has organized graduate medical courses given in English. The cost is generally $6 a lesson, whether taken privately or in a group, and, if there are six students, each one will pay $6 for the entire course. Special arrangements can be made for courses exceeding a week. Courses in dissection may also be arranged. All graduates will be able, without additional charge, to witness operations or accompany the attending physicians or surgeons of the Paris hospitals on daily ward walks. Daily bulletins, similar to those employed in the larger medical centers of the United States, announce the operations to be performed at about twenty hospitals. These bulletins can, on request, be sent by special delivery to the hotel or boarding house where the graduate is stopping or to the Cité universitaire (Maison américaine), where lodging and meals can be secured at very moderate rates. Thus the graduate can plan his program for the following day, having received the bulletin the preceding evening. The medical school of the University of Paris will grant certificates for graduate work of not less than two months' duration. Arrangements can be made by writing to A. D. R. M. (Salle Béclard), Faculté de médecine, 12 rue de l'Ecole de médecine, Paris, for private courses in English in rheumatology, otolaryngology, infantile neuropsychiatry, endocrinology, cystoscopy and urethroscopy, neurology, operative technic, parasitology, cardiovascular diseases, pulmonary tuberculosis, gastro-enterology and pediatrics. This is the first time that a systematic effort has been made here to give graduate courses in English. The clinical material and laboratories are equal if not superior to those accessible to graduates in other parts of continental Europe. The professors giving these courses include many physicians of international reputation.

March 6, 1939.

The Development of Bronchoscopy

"Forty Years of Bronchoscopy" is the title of a lecture delivered before the Berlin Medical Society by Professor von Eicken, Berlin ordinarius in otorhinolaryngology. His teacher, Professor Killian, was really the founder of this method. Eicken too, as successor of Killian, has participated in the development of the bronchoscopic technic. After the invention of the laryngoscope by Garcia in 1854, a tube was first introduced into the esophagus by the clinician Kussmaul in 1867. In the exercise of this method one of Kussmaul's pupils placed the tube too far forward and observed the bifurcation of the bronchi. Warnings against introduction of tubes into the respiratory tract were quite common at that time. First in 1897 Killian, then at Freiburg-in-Breisgau, made a practical application of his theories: by means of a specially constructed esophagoscope he removed an aspirated bone from the trachea. Thereafter other interventions of this type were made. The attempt was also made to advance a tracheotomy opening and thus to reach as far as the right inferior lobe. But the direct oral method came to be carried on only after step-by-step perfection of the instrumentation had taken place. In the year 1906 Professor von Eicken himself, who had for long collaborated with Killian, was able to report on 600 successful removals of foreign bodies from the respiratory passages. As the method developed, the attendant difficulties multiplied. In time the profession, growing better acquainted with bronchoscopy, came to recognize that, if an aspirated body could not be quickly removed by the general practitioner, the patient should as soon as possible, namely within the first few hours after aspiration, be placed in the care of a specialist skilled in bronchoscopic technics. At present bronchoscopy is almost an everyday operation; removals of foreign bodies are reckoned in tens of thousands. According to the latest American contributions, however, the removal of foreign bodies represents but a small fraction of the interventions for which bronchoscopy is indicated. In America the method is above all used in the abolishment of postoperative pneumonia. If signs suggestive of pneumonia appear during the first postoperative days, coagulum and mucus are removed with the aid of the bronchoscope and the patients are thus spared the dreaded pneumonic complication. In conclusion von Eicken pointed out that the dense shadows in the roentgenogram after aspiration of foreign bodies may be mistaken for signs of pneumonia. Foreign bodies may produce not only atelectasis but in addition a serous exudation in the alveoli and a venous congestion that is often of high grade. The heavy shadows are based on the sum of these phenomena. The amazingly rapid clearing of the lung picture (often within a few hours) after removal of the foreign body may be explained as due to speedy resorption.

Research on the Pathology of the Liver

Professor Nonnenbruch, Prague ordinarius in internal medicine, discussed his investigations on hepatic disease before the Frankfort Medical Society. Continuous checking of the residual nitrogen provides a good measuring rod of the course of the illness. Urea and residual nitrogen maintain an interrelation in that the latter diminishes as the urea is increased by oral administration of urea or because of renal insufficiency. Liver extracts can produce the same results; urea is therefore a therapeutic agent capable of promptly abolishing a hepatargic

condition. Residual nitrogen, however, provides no clue to the secret of a coma hepaticum that is unaccompanied by increase in residual nitrogen and rest nitrogen. Coma hepaticum is not accompanied by any characteristic blood picture. Frequently a renal insufficiency participates in this condition; the urea then rises to a high level. In other cases there is a greater increase in residual nitrogen. Many times the potassium values in the blood and the cerebrospinal fluid are greatly elevated, a sign of the subsidence of so-called regulated permeability; but cases of coma hepaticum are occasionally seen in which the potassium value in the serum remains normal. In one case in which massive intravenous injections of dextrose solution were exhibited a "water intoxication" was manifested. Like uremia, coma hepaticum is not to be interpreted in terms of one specific toxin but rather represents a complex of disturbances. The following primary classification may be made on the basis of the blood chemistry: (1) coma hepaticum with increase of the residual nitrogen only (amino-acidemia, azotemia II), (2) hepatorenal coma with azotemia III and (3) coma without azotemia and without significant phenomena in the blood chemistry.

A New Type of Balneotherapy

As every one knows, a search is in progress throughout Germany for new materials that lend themselves to utilization as substitutes. In this connection the following new type of balneotherapy is reported: At Ziegenhals, a small Silesian watering place, so-called wood-pulp slurry (holzschlamm) has been used as a bathing medium for some time. This slurry is a by-product of paper making. The municipality of Ziegenhals has applied to the national patent office for a protective patent of this therapy in the hope that in future the town will be the only place in Germany where visitors with rheumatism and sciatica can be treated with pulp-slurry baths. Last year 5,200 baths of this type were administered. Since Ziegenhals expects a much greater influx of patients during the current year, and since the present accommodations are no longer adequate, a new bath house is to be constructed equipped with at least ten cabinets and having a capacity of from eighty to a hundred baths daily. From the standpoint of economics it is also an interesting fact that the same slurry in which the patients bathe can again be utilized in the manufacture of paper. The foregoing notice is thus far the only extant news with regard to the new use of wood-pulp slurry. No clinical report has been published to date although the new method has received mention in medical journals.

The Nursing Sisters and Tuberculosis

Extensive recent examinations of more than 40,000 members of the nursing sisterhoods have demonstrated that the profession of nursing sisters, despite the fact that its members are exposed to greater dangers than most professionally active women, still is characterized in all parts of Germany by favorable expectation of life. However, in view of the increasing number of occupational illnesses on a tuberculous basis, especially among youthful employees of the tuberculosis wards of hospitals, the establishment of a minimum age limit for permission to work among tuberculous patients has been deemed expedient. Accordingly the accident prevention code of the association of health and welfare employees has been supplemented by a new stipulation to the effect that the care and surveillance of actively tuberculous patients should be entrusted only to healthy persons, capable of resisting infection, who are not less than the age of 25 years. It is also stipulated that the attending physicians and any other persons whose occupation requires contact with tuberculous patients must be in good health and not likely to become infected. The fixing of the age limit at 25 was dictated primarily by the consideration that initial infection with tuberculosis is not only much rarer after the twenty-fifth year of life, but is usually of a milder character, if acquired.

AUSTRALIA

(From Our Regular Correspondent)

March 14, 1939.

Australian and New Zealand Association for the Advancement of Science

The recent meeting of the Australian and New Zealand Association for the Advancement of Science was in part reported in THE JOURNAL April 15, page 1520. An illuminating contribution to the medical section was a joint discussion on virus diseases. The discussion centered largely round the controversy as to whether viruses are to be considered independent living organisms or not, and proceeded along two main lines, one suggested by Dr. F. M. Burnet, who has done research on animal viruses at the Walter and Eliza Hall Institute, Melbourne, the other by R. J. Best, M.Sc., of the Waite Agricultural Institute, Adelaide.

Dr. Burnet expressed the view that viruses are essentially independent living organisms. He said that with the present definition of viruses as particulate agents of disease smaller than bacteria and susceptible of being grown only on living cells of a host, it was difficult to believe that there were any natural biologic divisions among the micro-organisms of disease. Certain strictly parasitic bacteria could not be grown apart from living cells, while among the larger "true" viruses were many features of resemblance to bacteria. The nature of viruses could be examined from three points of view: 1. Physicochemical: Complete physicochemical formulation of even the simplest virus was not likely to be attained. 2. Pragmatic: An approach could be made by seeking the working hypothesis best suited to the practical needs of the virus, the research worker, the clinician and the veterinary or plant pathologist. 3. Evolutionary: Here there were three possibilities: (*a*) the virus was a pathologically active fragment of the cell it parasitized, (*b*) it represented a surviving form of a precellular stage of evolution or (*c*) it was a specialized or degenerate descendant of a larger parasitic micro-organism. This third hypothesis seemed to him most likely to be true. It provided an explanation of the graded series from bacteria to the smallest viruses. It was well known that the more highly parasitic bacteria were harder to grow in vitro, produced more specific types of disease, and showed a greater tendency to intracellular growth. The rickettsias were almost certainly derived from bacteria which had developed a symbiotic habit in arthropods. With development of complete parasitism, viruses had lost to a greater or less extent their complement of enzymes and now made use of the enzymes and activated molecules of the host cell. The types of virus now in existence represented various stages in this process of parasitic degeneration.

R. J. Best subscribed rather to the view that viruses represented a surviving form of primordial living matter. He showed that many plant viruses and at least one animal virus had been isolated as proteins and that virus particles had now been obtained which were actually smaller than some protein molecules. While it had not yet been shown that virus properties were not due to some impurity of the protein crystals obtained, this now seemed unlikely. He expressed the view that whereas the protein itself when isolated did not show properties particularly different from any other protein body or phenomena to suggest that it was living, nevertheless when placed in a suitable environment the protein in that environment constituted an independent living system which metabolized and developed at the expense of the normal metabolism of its host and that in such an environment the virus protein reproduced itself at the expense of the energy of its host cell. Countering the argument that such a conception presupposed a higher stage of evolutionary development in the environment and so eliminated the possibility that viruses might represent a primordial form of life, Best replied that viruses were not

recognized only by their biologic activity in their host organism. This did not preclude the possibility that virus proteins existed at the present time in non-living environments since, if they did so, there was no method of recognizing their existence. He concluded by saying that viruses, being a group of living molecules intermediate between the macromolecules of the chemist and the micro-organisms of the biologist, much cooperative investigation from the physical, chemical and biologic aspects was required to elucidate their nature.

TISSUE SPECIFICITY OF INFLUENZA VIRUS

The tissue specificity of influenza virus was discussed by Dora Leish, M.Sc., of the Walter and Eliza Hall Institute, Melbourne. Many viruses, of which the influenza virus was a good example, were rather strictly limited to one particular tissue, in this case the lining of the respiratory tract. This tissue limitation was also shown when the virus was grown on embryonic organs. Influenza virus grew best in the lung of chick and guinea pig embryos, although innocuous to the adults of these species. The more embryonic the tissue, the wider the range of organs that would allow growth. Studies of this kind might throw light on the nature of the interaction between virus and susceptible cell.

PRINCIPLES AND TECHNIC OF PUBLIC EDUCATION

Dr. N. M. Gutteridge, lecturer in bacteriology, University of Queensland, said that the constructive possibilities of science were not fully utilized by the existing social organization, although its destructive possibilities were only too hastily developed. Where science tended to fall short was in its failure to control the interpretation of its advances and their application to society. In modern science lay the hope of civilization, but before society could derive full benefit from the discoveries of science it must find a way of spreading scientific information geared down to the layman's power of understanding. Dr. Gutteridge stressed the growing significance of public education especially in the field of constructive medicine. Unfortunately, the agencies playing the greatest part in public education today were commercial advertising and the films. Between the two a colossal and unremitting pressure was brought to bear on the public mind, and the advent of organized education in fields such as nutrition and physical education had to contend with this pressure. To develop an enlightened public opinion, we had to learn to speak a new language in order to compete with those other influences dominated by commercial interests. That language must be a dramatic rather than a rational one, and the appeal must come as much through emotion as through reason. The process was largely one of interpretation, and in it well developed radio and film technic could prove a valuable medium. This statement was illustrated by means of the British nutrition film entitled "Enough to Eat" and a dramatized broadcast on nutrition.

HEALTH EDUCATION IN QUEENSLAND

Dr. Gutteridge then described the active public education campaign which had been carried on in Queensland over the the last three years under the egis of the Queensland Nutrition Council. Dramatized broadcast sessions on nutrition, on lines similar to those of the health talks conducted by the American Medical Association, had been broadcast regularly twice a week. Frequent articles had appeared in the metropolitan and country press, as well as a six page annual nutrition supplement in the *Courier Mail*. The council had published a "menu-planning chart" and a year book, each of which had been widely distributed, and several courses of lectures on everyday nutrition had been arranged. A weekly dramatized broadcast entitled "Healthward Ho!" had the approval of the Queensland branch of the British Medical Association, and a further weekly session, entitled "The Fitness Forum," dealt with the subject of physical education. Each of these sessions embodied the modern technic of dramatization. The work had been placed on a sound financial basis by enlisting the support of approved advertisers such as pasteurized milk companies. Already the effect of this education had been noticed in the changing food habits of Queensland people. Reliable figures were difficult to obtain, but commercial companies concerned reported a considerably increased demand in milk, fruit and salad vegetables as well as a specially prepared wheat germ bread over the last two years.

Jan. 1, 1939.

National Congress of Medicine

The sixth National Congress of Medicine took place at Córdoba Oct. 15-21, 1938. This congress meets once every four years. It is organized in several sections, which embrace the various branches of medicine. The general topic was "Organization of Public Health in Argentina." The advisability of making the various departments of public health only a body with a central board of directors was shown. Drs. G. N. Martínez, Gregorio Aráoz Alfaro, E. Bullrich, A. Bidau, Pedro Escudero, Alberto Zwanck and Alfredo Sordelli were speakers.

"Arterial Hypertension" was the topic discussed in the section on internal medicine. Profs. Franz Volhard of Frankfort, Carl J. Wiggers of Cleveland, Gregorio Marañón of Madrid, B. A. Houssay of Buenos Aires and G. N. Martínez, Temístocles Castellanos and Ramón Brandán of Córdoba were speakers. In the section on dermatology the immediate establishment of regional leprosariums was advised, and the speakers favored the support of the laws concerned with abolishing the recognition and regulation of prostitution. The main topics discussed in the sections on physiology and pharmacology were, respectively, "Sounds of the Heart and Electrical Phenomena of Nervous Energy" and "Agents for Chemical and Sympatheticolytic Transmission."

Annual Congress of Surgery

The Congreso Argentino de Cirugía held its tenth annual reunion Oct. 9-15, 1938, in Buenos Aires with Prof. J. M. Jorge as president. Among the surgeons present were Drs. Brandão, A. Monteiro, J. Poggi, M. Gudin, O. Gualberto, E. Linz, M. de Andrade and Aresky Amorim of Brazil; Luis Vargas Salcedo, E. Patermann, D'Alessandri, A. Bahauser, Fernández and Vargas Molinare of Chile; J. Mussio Fournier, A. Navarro, D. Pratt, C. Nario, C. Stanjano, V. Armand Ugon and E. Palma of Uruguay; C. R. Gagliardone of Paraguay, and A. Parada of Bolivia. South American surgeons consider it regrettable that North American surgeons do not attend this yearly congress. They would bring important contributions to the congress and at the same time see the progress made by the surgeons of South America.

HYDATID CYSTS

Prof. Oscar Ivanissevich spoke on the first topic, "Hydatid Cysts of the Lung." He advised artificial pneumothorax before the operation when the cyst is small and uninfected. The cyst is slowly evacuated to prevent its rupture in the bronchi or in the pleura. Ninety-two patients with hydatid cysts of the lung underwent operation at the Instituto de clínica Quirurgica, of which Professor Ivanissevich is a member, and the mortality rate was from 14 to 19 per cent. In ten cases cough or hemoptysis followed the operation. In fifty-five cases residual cavities of the lung were visible on x-ray examination.

MALIGNANT BONE TUMORS

Prof. Oscar Copello introduced the second topic, "Malignant Bone Tumors." He had adopted the Kolodny classification and discussed fifty-three cases, which included thirty of osteogenic

sarcoma, twelve of Ewing's tumors and twenty-one of metastatic tumors. He advised combined surgical and roentgen treatment. Profs. José Guardado and Diego Brachetto-Brian discussed the subject from roentgenologic and anatomopathologic angles.

Diminution in Birth Rate

The birth rate has diminished in Argentina, which is the richest and most prosperous country in South America. From 1887 to 1900 there were forty births for each thousand of population and from 1901 to 1914 thirty-five. The birth rate has diminished still more since the World War. In 1937 there were sixteen births for each thousand of population. In the last few years Buenos Aires, with a population of 2,400,000, has shown an alarming diminution in birth rate.

Personals

Drs. F. Arrillaga, Guillermo A. Bosco, José Valls and R. F. Vaccarezza have been appointed to the chairs of clinical medicine, semeiologics, orthopedics and tuberculosis of the Faculty of Medicine of Buenos Aires.

Drs. P. I. Elizalde and Gonzalo Bosch have been appointed members of the Academia Nacional de Medicina of Buenos Aires.

Drs. E. del Castillo, Alfredo Biasotti, Leopoldo Giusti, Gregorio Aráoz Alfaro and O. Orías were appointed official representatives of Argentina to the first South American Congress of Endocrinology at Rio de Janeiro.

Lectures

The following lectures have been delivered in Buenos Aires: Profs. F. H. Quix of Utrecht on the labyrinth; G. Duval of Paris on surgery; Georges Dumas of Paris on psychology; Cesare Frugoni of Rome on medical clinics, Franz Volhard of Frankfort on renal diseases; Paul Hübschmann of Düsseldorf on pathologic anatomy of tuberculosis; Carl Wiggers of Cleveland on fibrillation, resuscitation and hypertension; H. Arruga of Madrid on detachment of retina; Pedro Ara of Madrid on conservation of anatomic preparations, and Antoine Alajouanine of Paris on neurology.

BUDAPEST

(From Our Regular Correspondent)

March 19, 1939.

Poisoning with Caustic Potash

Dr. G. Faludi reported at a recent meeting of the Interhospital Association on his experience with children suffering from poisoning with caustic potash. Over a period of twenty-three years he treated in the children's wards of St. Stephen's Hospital 1,722 such patients, of whom 938 had acute intoxication and 784 were suffering from esophageal stricture. Of these patients 55.40 per cent were boys and 44.60 per cent girls; 60 per cent were from 1 to 3 years old. Of those with acute intoxication 19.19 per cent died, and of those suffering from stricture 13.40 per cent died. Of those with acute intoxication who died, 83.33 per cent died within three days after admission to the hospital. Ninety-eight per cent of all intoxications were the result of accidents, 1 per cent were suicide and 1 per cent were murder. Strictures most frequently occurred in the middle and the lower third of the esophagus. Dilation with the esophagoscope is not without danger. During the course of the twenty-three years Dr. Faludi met with twenty-six artificial perforations of the esophagus, of which five had occurred before the patient was admitted to the hospital. Early use of the sound must be resorted to with children. It is regrettable, said Faludi, that this method is not as extensively adopted as it deserves, because with it the most severe strictures can be successfully treated. For severe strictures not adapted to treatment with regular sounds, he used Hacker's retrograde treatment with a thread, preceded by gastrostomy. This treatment sometir takes years, but even in cases of severe stricture it is conduc to good results.

As treatment is at best unsatisfactory, prevention is m important. This can be accomplished only by applying dra measures to exclude from households the use of caustics. It not an uncommon experience for a mother to put the cau which resembles sugar cubes, into a tumbler of water bes the wash tub and then go to the kitchen to see about coo ing the dinner. The small child, seeing the sugar-like thing the tumbler, drinks it. Such mishaps ten years ago were daily occurrence. Now, through radical changes in packing t caustic, drastic restriction as to its sale and wide enlightenme of the public, the rate of accidents is decreasing; neverthele at present Hungary leads in the frequency of caustic intoxic tion. Faludi appeals to the government to stop the sale caustic potash.

The Sense of Taste

Dr. Harald Tangl, lecturer at the University of Budapest, a paper on the sense of taste said that taste is a regressi sense in man, as he tastes only with his tongue while son animals, e. g. fishes, taste with their whole body. An infa tastes with the middle part of his tongue and an adult dete mines with the sides of his tongue whether food is pleasing c not. The whale has very few taste buds and gulps its food s quickly that it does not bother about the taste. Among horne cattle, taste is important, and they scrupulously select th grasses they like. The cow has about 15,000 taste buds, th antelope 50,000 and man 3,000.

We know four distinct tastes: sweet, salty, bitter and sour The sweet taste is perceived on the tongue the quickest, becaus the buds reacting on sweets are located at the tip of the tongue; then comes salty and then sour taste. Bitter things are tasted at the back of the tongue. Taste can be regulated Warm coffee requires less sugar than cold, because warmth is a stimulant to the taste buds. However much sugar is put into ice cream it will not seem too sweet, because when cooled the taste buds scarcely function. If the tongue is rubbed with ice, one fails to perceive different tastes, a good method in taking bitter drugs. Taste is such a fine sense that it cannot be overtaken by chemical procedures. The taste can be trained. Tea tasters are able to tell the place of origin of a tea after a single tasting Wine tasters can tell from where a certain variety of wine came and also whether the grapes from which it was made grew in a sunny or a shady field.

Marriages

ELIZABETH WASHINGTON KIRBY-SMITH, Sewanee, Tenn, to Mr. David Culbreth Clough of Dover, Del., January 7.

THOMAS EDWARD CAULFIELD JR., Woburn, Mass., to Miss Mary Smith Carroll of Gloucester, Nov. 26, 1938.

THOMAS EDMOND HUGHES, Richmond, Va., to Miss Mary Elizabeth Warren of Delaplane, February 23.

KENNETH L. CARTER, St. Louis, to Miss Frances Elizabeth Ritter of Mattoon, Ill., in December 1938.

DAN ARTHUR JARDINE, Douglas, Ga., to Miss Charlotte Williams of Haddock recently.

DEANE C. EPLER, Detroit, to Miss Kathryn Louise McNeil of Tiffin, Ohio, Nov. 10, 1938.

ROLF VAN K. EGGERS, Seattle, to Miss Kathryn Johnson of San Francisco, Nov. 5, 1938.

RICHARD VINCENT EBERT to Miss Virginia Bordeau Benjamin, both of Boston, recently.

CALVIN G. JACKSON to Miss Mary Lou Johnson, both of Kenton, Ohio, in January.

CLAUDE R. G. FORRESTER to Miss Ruth Emma Johns, both of Chicago, January 5.

Deaths

Alfred Stengel ⊕ distinguished physician of Philadelphia and distinguished equally as a medical writer and educator, died at his home in Philadelphia, April 10, aged 70. He had been associated with the University of Pennsylvania as a teacher and administrator for forty-six years.

Dr. Stengel was born in Pittsburgh, Nov. 3, 1868. He received his M.D. degree from the University of Pennsylvania in 1889. Soon after graduation he became assistant to Dr. William Pepper. In 1893 he joined the faculty of the University of Pennsylvania as instructor in clinical medicine. In 1896 he became clinical professor of medicine at the Woman's Medical College of Pennsylvania, retaining this position until 1898. He became professor of medicine in the University of Pennsylvania in 1911, and vice president of the university in charge of medical affairs in 1931. In this position he not only supervised the School of Medicine and the Graduate School of Medicine and such auxiliary divisions as the Phipps Institute but also the Evans Institute of Dentistry and the School of Veterinary Medicine. He was president of the board of the Wistar Institute of Anatomy and term trustee of the University of Pennsylvania, member of the trustees' executive board, and the manager of the Veterinary Hospital.

ALFRED STENGEL, M.D., 1868-1939

In his career in medicine he received many honors, including the honorary degree of doctor of laws from the University of Pennsylvania at the 165th anniversary, the honorary degree of doctor of laws from Lafayette College, and the honorary degree of doctor of science from the University of Pittsburgh.

His literary contributions to medicine were numerous, including "A Text-Book of Pathology" which went to eight editions between 1898 and 1924. He served as editor at one time of the *American Journal of the Medical Sciences* and was a contributor of various sections or volumes in most of the leading systems of medical practice. Dr. Stengel was editor of the American edition of Nothnagel's Cyclopedia of Medicine.

For two terms Dr. Stengel was president of the American College of Physicians and he was a member of the Association of American Physicians, the Philadelphia Pathological Society, and numerous other medical organizations. He was also consulting physician to the Philadelphia General Hospital, the Jewish Hospital, the Abington (Pa.) Memorial Hospital, the Norristown State Hospital, and the Woman's College Hospital. At the time of his death he was actively concerned with the development of a new building for obstetrics and gynecology at the University of Pennsylvania and with new space for a department of neurology.

In the American Medical Association Dr. Stengel served as member of the House of Delegates in 1905 and he had been a member of the editorial board of the *Archives of Pathology*. With his death, medicine lost a great teacher devoted to the highest ideals in the field of medical science, a builder of medical institutions, a man who exemplified in his life and his work the manner in which the physician may contribute in the highest degree to the advancement of his profession.

Angus McLean ⊕ emeritus professor of surgery at Wayne University College of Medicine, died at his home in Detroit on April 11 of carcinoma of the stomach, aged 76. He had a long and distinguished career in the field of medicine and was equally notable for his service as a great citizen of Detroit.

Dr. McLean was born in St. Clair, Mich., April 4, 1862. He graduated from the Collegiate Institute of Strathroy, Ontario, in 1880 and received his M.D. degree from the Detroit College of Medicine in 1886. Later he served in various capacities in the city and state government, holding at different times the position of city physician, quarantine inspector for the Port of Detroit, member of the state board of health and member of the city board of health. In his work in the field of medicine he was past president of the Wayne County Medical Society and the Michigan State Medical Society and was first president of the Detroit Academy of Surgery. He was appointed in 1905 to serve on the state board of health and in 1911 was made a member of the Detroit Board of Health.

During the World War he organized and was commanding officer of the Harper Base Hospital No. 17 in France and was cited for heroic work in the American Expeditionary Forces. He became president of the Medical Commission and was sent to Italy in October 1917. Later he was transferred from hospital duty and appointed special surgeon to the Peace Commission in France. By special order of General Pershing, he accompanied President Wilson on his homeward journey in February 1919. The War Department conferred on him the Distinguished Service Medal. In 1927, he was one of four physicians appointed by President Coolidge to attend the Military Medical Congress at Warsaw, Poland, at which time the President of Poland presented him with a medal on behalf of the Polish Army Officers' Medical School of Warsaw. He was also made honorary professor of medicine by the University of Warsaw.

In 1929, he was one of five physicians appointed by President Hoover to represent the United States in the Fifth International Congress of Military Surgeons at London and at the Royal Institute of Public Health at Zurich, Switzerland. For his work abroad he was recognized by the award of the Chevalier of the French Legion of Honor. He was also made an honorary member of the Federation of Soldiers of France and a member of the Société Française. In 1936, he was awarded the Order of Knight Commander of the Crown of Italy.

Dr. McLean was conspicuous in the general field of education, having been a member of the Detroit Board of Education since 1923, and president of the board in 1935. He served as chairman of the Michigan committee for the relief of German children and was decorated by the German government for this work.

ANGUS MCLEAN, M.D., 1862-1939

In his work in surgery he made numerous scientific contributions to surgical periodicals. He was consulting surgeon to the Children's Free, Woman's, St. Joseph's Mercy, Receiving and Providence hospitals and the Florence Crittenton Home.

Dr. McLean's career was an exemplification of the opportunities that America has offered in the past and how a young man may rise from humble beginnings. His father was a farmer. Dr. McLean, at various times in his career, was a lumber mill employee, a dock hand, a ship's watchman, a Great Lakes sailor and a pilot. He retained his interest in sailing, having his own yacht. He took part in every activity for the advancement of his community and for the development of his profession.

William Belfry Hendry, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1904; professor emeritus of obstetrics and gynecology at his alma mater; member of the *American Association of Obstetricians, Gynecologists and* Abdominal Surgeons and the American Gynecological Society; fellow of the American College of Surgeons, Royal College of Surgeons of Canada and the British College of Obstetricians and Gynecologists; served during the World War; consultant in obstetrics to the Toronto Board of Health and Federal Board of Health; consultant in obstetrics and gynecology to the Provincial Board of Health; on the staff of the Toronto General Hospital; aged 64; died, March 24, of leukemia.

James Francis Lynch ⊛ Hartford, Conn.; College of Physicians and Surgeons, Baltimore, 1913; fellow of the American College of Surgeons; aged 46; attending surgeon to St. Agnes' Home and House of the Good Shepherd; consulting surgeon to the Hartford Neuro-Psychiatric Institute and Hospital; consulting supervisor of surgery, Veterans Administration Facility, Newington; attending surgeon to St. Francis Hospital, where he died, January 7, of gastric hemorrhage.

Arthur Daniel Kurtz ⊛ Philadelphia; Jefferson Medical College of Philadelphia, 1908; formerly associate professor of orthopedic surgery at Temple University School of Medicine; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; on the staffs of the Misericordia Hospital, Jefferson Hospital and the Homewood School; aged 52; died, January 21, of essential hypertension and acute hemorrhagic nephritis.

Francis D. Pringle ⊛ Punxsutawney, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; past president of the Jefferson County Medical Society; for many years president of the city board of health and of the board of education; for fifteen years county health officer; aged 67; on the staff and formerly superintendent of the Adrian Hospital, where he died, January 29, of uremia.

William Lee Helms, Taylor, Texas; Louisville (Ky.) Medical College, 1904; member of the State Medical Association of Texas; past president of the Williamson County Medical Society; formerly city health officer and member of the school board; on the staff of the Wedemeyer Hospital; aged 68; died, January 2, in a hospital at Temple of injuries received in an automobile accident.

Arthur Guernesey Root, Albany, N. Y.; Albany Medical College, 1890; member and past president of the Medical Society of the State of New York; at one time professor of diseases of the throat and nose at his alma mater; member of the American Laryngological, Rhinological and Otological Society; formerly on the staff of the Albany Hospital; aged 71; died, February 26, of myocarditis.

Hugh Forsythe Lorimer ⊛ Englewood, Colo.; Columbus Medical College, 1883; in 1908 member of the House of Delegates of the American Medical Association; past president of the Ross County (Ohio) Medical Society; formerly member of the state board of health; aged 81; died, January 9, in the Presbyterian Hospital, Denver, of chronic myocarditis and paralysis agitans.

William Converse Kendall, Freeport, Maine; Georgetown University School of Medicine, Washington, D. C., 1896; for many years associated with the U. S. Bureau of Fisheries; was a member of the MacMillan Arctic Expedition; aged 77; died, January 28, in a hospital at Mobile, Ala., of intestinal obstruction and carcinoma of the rectum.

Brayton Eugene Kinne, Albany, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1901; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; visiting surgeon to the Memorial Hospital; aged 61; died, January 23, of arteriosclerosis, endarteritis obliterans and coronary disease.

George Quincy Johnson, Ardsley, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882; member of the Medical Society of the State of New York; medical officer of the public schools; aged 79; on the staff of the Dobbs Ferry (N. Y.) Hospital, where he died, January 23, of coronary thrombosis.

Maurice Louis Goodkind ⊛ Chicago; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; professor of medicine at the University of Illinois College of Medicine; served during the World War; for many years on the staff of the Michael Reese Hospital; aged 71; died, January 4, of coronary occlusion.

Arthur Ernest Hale ⊛ Alva, Okla.; University of Kansas School of Medicine, Kansas City, Kan., 1913; past president of the Woods County Medical Society; served during the World War; aged 52; on the staff of the Alva General Hospital, where he died, January 11, of gas bacillus infection, following operation for ruptured diverticulum.

Willis Harland Flamm, Amarillo, Texas; John A. Creighton Medical College, Omaha, 1908; member of the State Medical Association of Texas; past president of the Potter County Medical Society; on the staffs of the Northwest Texas Hospital and St. Anthony's Hospital; aged 56; died, January 8, of heart disease.

William Wallace Larsen, ⊛ Le Mars, Iowa; State University of Iowa College of Medicine, Iowa City, 1913; member of the Iowa State Medical Society and the Radiological Society of North America; on the staff of the Sacred Heart Hospital; aged 55; died, January 19, of rhabdomyosarcoma with metastasis.

James Elmer Donnell, Cuba City, Wis.; Illinois Medical College, Chicago, 1907; member of the State Medical Society of Wisconsin; past president of the Grant County Medical Society; served during the World War; aged 62; died, January 19, in Dubuque, Iowa, of intestinal obstruction and carcinoma of colon.

John Frank Hastings ⊛ Kenosha, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; past president and secretary of the Kenosha County Medical Society; on the staff of the Kenosha Hospital; aged 61; died suddenly, January 17, in Chicago, of chronic myocarditis.

Henry Wellington Cook, Hicksville, Ohio; Western Reserve University Medical Department, Cleveland, 1895; member of the Ohio State Medical Association; formerly member of the board of education of Hicksville and of the county board of education; aged 73; died, January 7, of bronchopneumonia.

Margaret Rodgers James, Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1929; member of the Medical Society of the State of Pennsylvania; on the staff of the Allentown Hospital; aged 35; was found dead, January 21, of injuries received in an automobile accident.

Joseph Edward Evans ⊛ P.A.S., Lieutenant, U. S. Navy, Charleston, S. C.; Harvard University Medical School, Boston, 1927; fellow of the American College of Surgeons; entered the navy in 1927; served during the World War; aged 40; died, January 25, in the United States Naval Hospital.

Raymond Barzillia Burr, Blair, Neb.; University of Nebraska College of Medicine, Omaha, 1927; member of the Nebraska State Medical Association; served during the World War; aged 42; died, January 9, in the Immanuel Hospital, Omaha, of coronary occlusion and arteriosclerosis.

Augustus William Hendricks, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; past president of the Lehigh County Medical Society; formerly city health officer; aged 70; died, January 31, of coronary embolism.

Clarence Paul Johnson, San Antonio, Texas; Baylor University College of Medicine, Dallas, 1929; member of the State Medical Association of Texas; on the staffs of the Nix and Robert B. Green Memorial hospitals; aged 38; died, January 14, when he fell from a twenty-one story window.

Marshall McDowell ⊛ Cynthiana, Ky.; Medical College of Ohio, Cincinnati, 1894; treasurer of the Kentucky State Medical Association; past president of the Harrison County Medical Society; on the staff of the Harrison Memorial Hospital; aged 66; died, January 26, of cerebral hemorrhage.

George Hazard Crooker ⊛ Providence, R. I.; Harvard University Medical School, Boston, 1893; veteran of the Spanish-American and World Wars; formerly on the staff of the Rhode Island Hospital; aged 73; died, January 12, of coronary thrombosis and bronchopneumonia.

John Alexander Jackson, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; member of the Medical Society of the State of New York; aged 77; died, January 11, in St. Joseph's Hospital, Tampa, Fla., of cerebral hemorrhage.

George Stillman Clark, Worcester, Mass.; Harvard University Medical School, Boston, 1885; member of the Massachusetts Medical Society; aged 79; died, January 26, in the Memorial Hospital of arteriosclerotic gangrene followed by amputation of the left leg.

Francis Orman Hill, Monticello, Maine; Medical School of Maine, Portland, 1899; past president of the Aroostook County Medical Society; formerly member of the state legislature; aged 66; died, January 2, of coronary occlusion and cerebral hemorrhage.

William Henry Emery, Boston; Harvard University Medical School, Boston, 1870; member of the Massachusetts Medical Society; Civil War veteran; aged 90; died, January 21, in the Veterans Administration Facility, Bedford, Mass., of myocarditis and arteriosclerosis.

William T. Fitzgerald, Greenville, Ohio; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1891; formerly congressman; aged 79; died, January 12, of arteriosclerosis and streptococcic throat infection.

Guy Goodwin Fernald, West Concord, Mass.; Dartmouth Medical School, Hanover, N. H., 1899; member of the Massachusetts Medical Society; for many years on the staff of the Massachusetts Reformatory Hospital; aged 74; died, January 21,

Charles Whitefield Clark, Toronto, Ont., Canada; Hahnemann Medical College and Hospital, Chicago, 1866; Homeopathic Medical College of Missouri, St. Louis, 1867; aged 93; died, January 8, of carcinoma of the pancreas and duodenum.

Earle Wayne Cliffe, Youngstown, Ohio; Cleveland Homeopathic Medical College, 1909; member of the Ohio State Medical Association; served during the World War; aged 54; died, January 31, in St. Elizabeth's Hosptial of angina pectoris.

Charles Alexander Eastman, Detroit; Boston University School of Medicine, 1890; at one time inspector in the Indian Service of the U. S. Department of Interior; aged 80; died, January 8, of bronchopneumonia and chronic myocarditis.

John W. Cooper, Kempton, Ind.; Physio-Medical College of Indiana, Indianapolis, 1884; member of the Indiana State Medical Association; aged 80; died, January 23, in St. Francis Hospital, Beech Grove, of carcinoma of the stomach.

William E. Howell, Gallipolis, Ohio; Medical College of Ohio, Cincinnati, 1897; member of the Ohio State Medical Association; formerly county health officer; aged 70; was found dead in his automobile January 21, of heart disease.

Mark Jacob Gottlieb ⊕ New York; University and Bellevue Hospital Medical College, New York, 1909; on the staffs of the Beth Israel Hospital and the Hospital for Joint Diseases; aged 53; died, Dec. 21, 1938, of heart disease.

William Levi Ward, Victoria, Texas; University of Louisville (Ky.) Medical Department, 1880; aged 86; died, Dec. 27, 1938, in a local hospital of cerebral injuries received in an accidental fall down the stairway of his home.

George Benjamin Henke ⊕ Ontario, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1913; on the staff of the San Antonio Community Hospital, Upland; aged 54; died, January 25, of coronary occlusion.

Earl Berton Fitzpatrick ⊕ Martinez, Calif.; Oakland (Calif.) College of Medicine and Surgery, 1910; served during the World War; aged 51; died, Dec. 9, 1938, in the Community Hospital of tuberculosis of the bladder.

Frederick Leslie Dod, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1904; member of the Missouri State Medical Association; served during the World War; aged 62; died, January 30, of pneumonia.

Arthur Wayland Howard, Wethersfield, Conn.; University of the City of New York Medical Department, 1890; member of the Connecticut State Medical Society; aged 71; died, January 16, of coronary thrombosis.

Theodore A. Erck, Leesburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; fellow of the American College of Surgeons; aged 75; died, January 10, of carcinoma of the mesentery.

William F. Finney, Trenton, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; aged 90; died, January 18, in St. Francis Hospital of prostatic hypertrophy and bronchopneumonia.

George W. Clayton, Laurel, Miss. (licensed in Mississippi in 1906); member of the Mississippi State Medical Association; on the staff of the Laurel General Hospital; aged 57; died, January 13, of angina pectoris.

Julius Arthur Dosher, Southport, N. C.; Baltimore Medical College, 1903; served during the World War; aged 59; on the staff of the Brunswick County Hospital, where he died, January 10, of pulmonary tuberculosis.

John Clifton, Vermillion, Kan. (licensed in Kansas in 1901); member of the Kansas Medical Society; formerly county health officer; aged 74; died, January 16, in Topeka of myocardial and renal insufficiency.

Rufus Peabody Hubbard, New York; Harvard University Medical School, Boston, 1883; aged 82; died, January 7, in St. Luke's Hospital of chronic glomerular nephritis and lobar pneumonia.

Clarence Denver Potter, San Francisco; Hahnemann Hospital Collge of San Francisco, 1896; member of the California Medical Association; aged 66; died, Dec. 8, 1938, of arteriosclerosis.

Horace Everett Doughty, Oxford, Maine; Baltimore Medical College, 1909; formerly member of the school board; aged 65; died, January 28, of nephritis and diabetes mellitus.

Jesse Willis Amey, Schenectady, N. Y.; University and Bellevue Hospital Medical College, New York, 1907; aged 67; died, January 11, in Miami, Fla., of cerebral hemorrhage.

Davis Leslie Askren, Fayoum, Cairo, Egypt; Central Medical College of St. Joseph, Mo., 1896; medical missionary; aged 65; died, January 18, of heart disease and emphysema.

Louis Philippe Dumont, Montreal, Que., Canada; Laval University Faculty of Medicine, Quebec, 1919; aged 43; was found dead, January 7, of poison, self administered.

Charles L. Baskin, Bremen, Ga.; Atlanta Medical College, 1895; member of the Medical Association of Georgia; aged 69; died, January 13, of uremia and paralysis agitans.

Patrick Joseph Brice, New Castle, Pa.; Jefferson Medical College of Philadelphia, 1907; aged 62; died, Dec. 17, 1938, in the New Castle Hospital of coronary occlusion.

Wilmer Kieffer Maglaughlin, Altoona, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; aged 71; died, Dec. 23, 1938, of cerebral hemorrhage.

Anna Beauregard Searcy Bourne, Springfield, Mo.; University of Missouri School of Medicine, Columbia, 1900; aged 76; died, January 14, of coronary thrombosis.

Daniel Burleigh Parkhurst, Ogunquit, Maine; Hahnemann Medical College and Hospital of Philadelphia, 1900; aged 79; died, Dec. 29, 1938, in Boston of myocarditis.

Joseph Leal d'Azevedo, Oakland, Calif.; College of Physicians and Surgeons, San Francisco, 1901; aged 63; died, Dec. 18, 1938, of arteriosclerotic heart disease.

John Aloysius Barry, Boston; Georgetown University School of Medicine, Washington, D. C., 1891; aged 77; died, Dec. 9, 1938, of carcinoma of the intestine.

George Howard White ⊕ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1906; aged 57; died, Dec. 21, 1938, of carcinoma of the colon.

Charles Cochran Kemble ⊕ Erie, Pa.; Jefferson Medical College of Philadelphia, 1897; aged 62; died, Dec. 24, 1938, in St. Vincent's Hospital of liver abscess.

Oliver R. Fore, Canton, Miss.; Atlanta College of Physicians and Surgeons, 1902; served during the World War; aged 63; died, Dec. 23, 1938, of gastric ulcer.

Cassius M. Clay, Milton, Fla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1897; aged 83; died, Dec. 26, 1938, of endocarditis.

"RELATION OF PHYSICAL EXERTION AND EMOTION TO PRECIPITATION OF CORONARY THROMBI"

To the Editor:—In an article entitled "Relation of Physical Exertion and Emotion to Precipitation of Coronary Thrombi" in THE JOURNAL, March 11, Dr. J. C. Paterson categorically stated that coronary thrombi are precipitated by exertion and emotion. This is contrary to our observations previously published in THE JOURNAL and elsewhere.

In the summary the author states that "activities of a patient immediately preceding the onset of an attack of coronary thrombosis have no relation to the etiology of the precipitation of a thrombus but are purely coincidental." Yet the very next sentence is "The pathologic appearances in a series of fatal cases of coronary thrombosis suggest strongly that exercise and emotional stress are intimately concerned in the mechanism of coronary artery thrombosis." These statements are contradictory.

If the author means unusual activities a few hours to a few days prior to the closure rather than the activities immediately preceding it, we have his statement with regard to his two cases that "both persons were pursuing their ordinary activities until just before their fatal attacks, and patient 2 was known to have been without complaints and in good spirits three and one-half hours before his death." Hence the author cannot believe that effort immediately or sometimes before the occlusion was a factor.

Although the author states that "on purely pathologic grounds there is reason to believe that such physical and mental states, both of which result in temporary hypertension, cannot be excluded as precipitating factors of coronary thrombi," he actually gives purely theoretical arguments but neither pathologic nor clinical evidence. Our belief that coronary artery occlusion is not related to activity or emotional stress was based on carefully elicited histories in 800 ward and private cases and not on theoretical discussion of blood pressure.

The author assumes that subintimal hemorrhage, with which it is now agreed coronary occlusion is usually associated, is produced by exertion or emotion resulting in an increase in blood pressure in the subintimal capillaries. There is no proof for this assumption. Leary and other investigators have shown, and Paterson himself has corroborated, that subintimal hemorrhages are part of the progressive arteriosclerotic process in the coronary arteries; it is unnecessary to invoke a rise in blood pressure to explain them. As a matter of fact, Winternitz found it necessary to perfuse the coronary arteries at pressures of from 500 to 1,000 mm. of mercury in order to outline the subintimal capillaries. In spite of these enormous pressures, far beyond any figure attained in hypertension, rupture of the capillaries did not occur, although severe coronary sclerosis was present. Furthermore, we have now collected a group of forty patients who because of the presence of carcinoma, heart failure and the like had been in bed for weeks or months prior to the attack of coronary artery occlusion. In spite of the absence of effort in such persons, subintimal hemorrhage was just as common as in others going about.

Paterson's two cases indicate that in some instances a varying period may elapse between the onset of thrombus formation and the clinical attack. This is not a new idea at all, having been noted by a number of writers including Levy and Bruenn in THE JOURNAL in 1936. We realized therefore that it was necessary to know the activity of the patient for some time prior to the acute episode, and in the last 250 cases we have analyzed the activities of the patient during the entire four weeks prior to the attack. These data have confirmed our belief that activity plays no role in precipitating coronary thrombosis. Not only did the attack begin at rest, as a rule, but there was no history of undue exertion or emotion previously. The occurrence of coronary artery occlusion in the forty patients who had been bedridden for weeks and months is confirmatory evidence of this.

It seems reasonable to us to collect clinical facts and to correlate them with the pathologic observations or with some tested physiologic mechanism. Paterson has completely ignored the clinical facts. These can be obtained by any one who takes a detailed history of the events preceding an attack of coronary artery occlusion. He will be struck by the fact that classic coronary artery occlusion almost invariably occurs in the absence of effort, excitement and trauma. In 1,400 cases we found the activities associated with coronary artery occlusion as follows:

Sleep	22.3	53.4%
Rest	31.1	
Mild activity	20.2	44.5%
Moderate activity	8.5	
Walking	35.8	
Unusual exertion	2.0	2.0%

This trifling association of coronary artery occlusion with unusual exertion eliminates it as a factor in the precipitation of the attack; otherwise coronary artery occlusion should occur very much more frequently for all of us, including those with coronary artery sclerosis who exert themselves during the day. If effort or excitement were a factor in the onset of coronary occlusion, sufferers from coronary sclerosis would never dare to move, read a newspaper or listen to the radio.

Since coronary artery occlusion occurs usually at rest or during sleep, it is even possible to explain subintimal hemorrhage on the basis of a drop in blood pressure and not on a rise, as Paterson assumes. It has long been known that, in shock with a fall of blood pressure, capillary hemorrhages are present throughout the body. In patients with severe coronary sclerosis, bleeding from an ulcer, for example, may produce coronary insufficiency and death. There is a fall of blood pressure concomitant with the exsanguination and yet fresh subintimal hemorrhages may be found post mortem.

We found not only that physical activity or emotional stress was not a factor in the onset of coronary artery occlusion but that occupation also played no role, attacks being equally common in laborers and persons engaged in sedentary occupations. This further corroborates our belief.

TUMORS IN TWINS

To the Editor:—I am making an analysis of records of tumors in twins and would be glad if you could lend me assistance by publishing this appeal for information to the medical profession of America:

A number of records have been published of tumors occurring in one or both members of a pair of twins. There is a divergence of opinion as to the conclusions that can be drawn from such reports. I am therefore asking all members of the profession who have had occasion to diagnose or treat tumors, either benign or malignant, in either one or both members of a pair of twins to communicate with me, giving the following information as far as possible:

Twin 1. Name Sex Tumor? Site Type
Age of onset Age at death Age, if still living
Was there operative or pathologic confirmation of the diagnosis?
Twin 2. Same information.

If the twins were of the same sex, were they so similar in appearance as to cause confusion in identity or were they dissimilar?

Those cases in which only one twin was affected are just as important as those in which both twins have the tumor. The names are important but will be kept confidential, because if the same person was treated by several physicians, all of whom were to send in information, the name would aid in checking the fact that there was a duplication. The age at the time tumor arose and the age at death or at which the twins are still living is of great importance also. If the tumor began in twin 1 six months ago and twin 2 has not yet shown it, the short duration of time must be considered in evaluating the record; but if the second twin has lived twenty years without the tumor developing, that point should be noted. Because there are not many available records of tumors in twins, I appeal to all members of the profession who read this note to send to me as soon as possible any data which they have on tumors in twins.

Medical School, University of Western Ontario.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VITAMINS IN GREEN AND RIPENED FRUITS

To the Editor:—What difference is there in the vitamin potency of tree-ripened fruit and fruit picked green and allowed to ripen?

LEONARD T. CARLSON, M.D., Minneapolis.

ANSWER.—This question cannot be answered categorically because there is a paucity of information on the subject and other important considerations are implied by the question. Most of the studies relating to ripening of fruits and the vitamin content have been made on tomatoes and oranges, and some of them have been confined to vitamin C. It has been reported that fully matured but green tomatoes are lower in vitamin A and vitamin C than vine-ripened fruit and that green fruit when ripened in the air shows some increase in vitamins A and C but does not acquire the same vitamin content as tomatoes ripened on the vine. There appear to be no important changes in the vitamin B content during the process of ripening, irrespective of method.

Two rather extensive studies on oranges show that if the fruit is picked in the early stages of maturity (state laws require that a certain acid-sugar ratio must be reached in the juice before interstate shipment is permitted) the vitamin C content of the juice is fully equal to that reached at any later stage of maturity.

Treatment with ethylene gas or the gas from oil heaters is extensively used to change the color of immature fruit to that of naturally ripened fruit. It appears that the only important change produced by this treatment is a bleaching of the chlorophyll so that the color of naturally ripened fruit is produced. This process does not alter the vitamin content of the fruit.

The generalization may be made that fruit shows a lowering of vitamin C during storage, but there are no important changes with respect to the other vitamins. It is improbable, however, that the metabolic changes during storage proceed to an important degree during the period required for ripening after the fruit has been picked. It is not possible to state with assurance that from a practical standpoint there is a measurable advantage in consuming fully tree-ripened fruit as compared with fruit picked at such a stage of maturity that it can be ripened off the tree.

The vitamin C content of fruits is discussed in the paper "Vitamin C Methods of Assay and Dietary Sources" by Otto A. Bessey, THE JOURNAL, Oct. 1, 1938, page 1290.

SALT SUBSTITUTES AND NEPHRITIS

To the Editor:—Is it the sodium or chloride ion that is advised against in the treatment of renal conditions associated with edema? I thought it was the sodium ion that was the detrimental factor. If the sodium factor, then would not that be contraindicated in the use of commercial "Curtasal"-Winthrop? This is advised for use to flavor foods when the use of salt is not advised. It contains, they say, "sodium formate with the addition of a small amount of magnesium citrate and calcium formate." What might one use advantageously to flavor foods when regular salt is not advised?

M.D., Wisconsin.

ANSWER.—The early work on the relation between salt retention and edema laid undue emphasis on the chloride ion, largely because of the difficulty of analyzing for sodium. When it was later demonstrated that potassium chloride, calcium chloride and ammonium chloride actually produced diuresis in edematous patients, emphasis was shifted to the cation sodium. Further work on clinical and experimental states of dehydration and hydration, or edema, revealed a quantitative relation between sodium and water excretion or retention, respectively. However, the conclusion that the chloride ion is unimportant in edema in comparison with the sodium ion is not justified. It is much easier, other things being equal, to produce edema with sodium chloride than with the equivalent amount of sodium bicarbonate. This follows from the normal composition of body fluids, in which there is about four times as much chloride ion as bicarbonate ion. The antiedemic effect of other chlorides than sodium chloride is undoubtedly due as much to the inability of the body to retain sodium without chloride as to the inability to retain chloride without sodium. Therefore, both sodium and chloride should be restricted in the treatment of edema.

Commercial substitutes for salt usually contain sodium and calcium compounds of formic, malic or amino acids. These are partly excreted unchanged but largely converted into bicarbonates. Since sodium bicarbonate is less edema producing than sodium chloride, the moderate use of these salt substitutes may not harm the patient in spite of the theoretical objection to sodium intake.

Any salt-free condiment or flavoring agent may be allowed to an edematous individual. Pepper, vinegar, lemon juice, onion, paprika and cinnamon can be suggested. D-glutamic acid, which is converted to urea in the body, has been recommended in doses of from 5 to 10 Gm. a day. The sodium salt contains only one third as much sodium as sodium chloride, per gram, and is seven times as salty. This salt has been used extensively in Chinese cooking. Both d-glutamic acid and its sodium salt are available commercially in pure form.

According to information received from the Winthrop Chemical Company by the Council on Pharmacy and Chemistry, Curtasal is composed of sodium formate 98 per cent, magnesium citrate 1 per cent and calcium formate 1 per cent. This preparation has not been submitted to the Council or examined by the Chemical Laboratory.

ANTIGEN-ANTIBODY REACTIONS—DENATURED PROTEINS

To the Editor:—1. Has any successful concentration of antibodies been obtained by attempted separation of antibody from antigen? 2. Can a denatured protein be restored to its native state? I have a recollection that Anson and Mirsky made some attempts along this line.

ALBERT ZRUNEK, M.D., Chicago.

ANSWER.—1. This question can be considered from two points of view: first, whether the reaction between antigen and antibody is a chemically reversible reaction in the sense that in a mixture of the two substances an equilibrium is attained in which the speed of combination is equal to the speed of dissociation, and, second, whether the isolated product of the reaction of antibody and antigen, in the form of either sensitized bacteria or cells, or precipitate from precipitin reaction, can be separated by manipulation into its component parts.

Reversibility in antigen-antibody reactions has been the subject of much experimentation and is discussed in such publications as "Infection and Resistance" by Hans Zinsser and "The Chemistry of Antigens and Antibodies" by Marrack. Madsen, Arrhenius and Ehrlich proposed that the basic laws of chemical equilibrium and mass action applicable to the reaction of acids and bases can find their analogies in serologic reactions. On the other hand there are facts that are inconsistent with these theories, such as the Danyz phenomenon, in which there is a

different result when the same quantity of antigen is mixed with a given quantity of antibody and when it is mixed in divided amounts, and the observation that the precipitate from precipitin reactions does not always dissolve in excess of antigen as would be expected in true equilibriums. The fact does remain, however, that the combination of antigen and antibody is in some instances clearly reversible, as shown by the following experiment: If an amount of red cells is saturated with hemolytic amboceptor, washed free of excess of this reagent and then mixed with an amount of untreated red cells, all the red cells, both the original and the newly added ones, can be shown to be sensitized by the hemolysis following the addition of complement. The only explanation of this phenomenon is that red cells may combine with more amboceptor than is necessary for hemolysis but will give up the excess amboceptor in the presence of unsensitized red cells.

The combination of antigen and antibody may be destroyed by various manipulations. The efficacy of neutral mixtures of diphtheria toxin and antitoxin as immunizing agents indicates that in the body the toxin is slowly released from its combination with antitoxin. The readiness with which this combination can be broken up is illustrated also by the incident which occurred a few years ago when a commercial product of diphtheria toxin-antitoxin became highly toxic after it had been frozen. The precipitate from precipitin reactions and cells and bacteria sensitized with their corresponding immune serums can be treated with various reagents so as to release the bound antibody. Hypertonic or relatively strong alkaline solutions are usually employed and use is made of the method to obtain highly purified antibody solutions. Heidelberger and Kendall (*J. Exper. Med.* **64**:161 [Aug.] 1936) in this way obtained from the precipitate formed with pneumococcus polysaccharide and antipneumococcus serum a solution of antibody in which 93 per cent of the nitrogen belonged to the immune bodies.

2. Denaturation of proteins, in contradistinction to precipitation, carries with it the idea of permanence. The actual chemical changes that occur in the process of denaturation are consistent with this idea. While there are some writers who say that denaturation is a reversible process, they base their assertion solely on the fact that some, but by no means all, denatured proteins can be redissolved. But there have been few attempts to show that the properties of the redissolved protein are identical with the native protein. The best evidence on this point is obtained by immunologic means. Theoretically, denatured proteins should be antigenic because they are digestible, since digestibility and antigenicity are closely parallel. However, the insolubility of denatured proteins interferes with their antigenic properties. When resolution of denatured proteins can be accomplished without secondary alterations due to the solvent, or when denaturation can be produced without coagulation, the proteins can be used as antigens. In such instances the immune reactions have shown that in most cases denaturation results in marked changes in specificity and this, in turn, denotes changes in the chemical structure of the proteins. From this evidence it is probable that recovery of native properties of proteins after denaturation does not occur.

CEREBRAL TRAUMA AND DUODENAL ULCER

To the Editor:—I understand that a gastric or duodenal ulcer can be a sequel to a severe head injury. Please enlighten me on this subject and give references.

M.D., Manitoba.

ANSWER.—The relation between intracranial lesions and gastrointestinal ulcerative processes, according to Cushing's review of the subject (Peptic Ulcer and the Interbrain, *Surg., Gynec. & Obst.* **55**:1 [July] 1932), was first suggested by Carl Rokitansky as early as 1841. Within the last decade there have been several reports of brain tumors, operations and accidents with gastrointestinal ulcerative processes, and experimental evidence of this possible relationship has been produced.

Cushing reported three cases of acute perforating gastrointestinal lesions which followed operations for cerebellar tumors. He also cited two cases of gastric erosions following operations for brain tumor, two cases of gastric ulcer associated with malignant hypertension with choked disks, the case of a child of 10 with chronic cicatrizing duodenal ulcer associated with a recurring cerebellar tumor, and the case of a man with duodenal ulcer who had a recurrence of gastric distress associated with each of three exacerbations of intracranial symptoms from a radiosensitive tumor encroaching on the third ventricle.

Vanzant and Brown (*Am. J. Digest. Dis.* **5**:113 [April] 1938) described the case of a well nourished, healthy boy of 11 who was hit by a truck, taken to the hospital, treated for concussion for four days, and returned to school in another ten days. Twenty days after the accident his appetite failed and on eating he noticed pain in the epigastrium. Six weeks after the injury a diagnosis was made of contusion and laceration without localizing signs. There was a spinal fluid pressure of 180 mm. of water, and blood in the stools. Fluoroscopic examination showed a small, irritable, constantly deformed duodenal bulb. A diagnosis of duodenal ulcer was made and the symptoms disappeared on ulcer management.

SPASTIC QUADRIPLEGIA—TOXIC NEURITIS

To the Editor:—1. A white woman aged 50, seen two weeks ago, first noticed difficulty in talking about one year previously. This has gradually increased until now her speech is indistinct. Then she noticed a stiffness of her arms and later of her legs. The paralysis of the legs has progressed so that now she cannot walk and can only with great difficulty move the arms or legs at all. Mentally she seems alert and active but cannot use the muscles of speech to express herself. The blood pressure is 134 systolic, 90 diastolic; the pulse rate is 96. Physical examination shows spastic quadriplegia. She sits with her arms flexed and hands closed. As she sits, her legs tend to straighten out stiffly. The feet are inverted by muscular pull. The extremities show lead pipe rigidity, with greater resistance to flexion than to extension. The left side is more involved than the right. The Babinski reflex is present on the left side; no tremor is present; the fingers can be straightened passively but resist straightening. The Wassermann reaction is negative. The pupils are equal and react well to light. What is the most probable diagnosis? Could a brain tumor cause this? What line of treatment would be advisable? 2. A man about 50 years old has recently returned from Florida. While there he worked removing "bootjacks" from the trunks of some palmetto trees. Shortly after he developed a tingling and pain in both hands and arms. Following this he developed muscular weakness of both forearms and hands. The patient feels sure that this resulted from a poison in the muck under the bootjacks. Have cases of a toxic neuritis ever been reported caused by this? He worked a total of only fifteen or twenty hours. What is the probable duration of this condition and the best line of therapy?

M.D., Washington.

ANSWER.—1. The gradually increasing spastic quadriplegia in a patient 50 years of age without signs of arterial disease, over a period of two years, is suggestive of one of the degenerative diseases of the nervous system. The diagnosis is probably paralysis agitans without tremor. This would account for the speech defect as well as for the spastic paralysis of all four extremities. It would not, however, quite satisfy the finding of "lead pipe" rigidity or the presence of the Babinski reflex on the left side. The rigidity of paralysis agitans is not of the lead pipe type but gives rise, when passive motion is used, to the cog-wheel type of stiffness. The so-called lead pipe type is ordinarily confined to diseases of the pyramidal tract, paralysis agitans being one in which the extrapyramidal tracts are involved, including the motor cells in the basal ganglions of the brain and possibly elsewhere. The Babinski sign, moreover, is indicative of pyramidal tract disease and would not be found in the ordinary case of paralysis agitans. If these two signs are substantiated by repeated examination, another cause for the patient's symptoms should be sought.

The slow onset and progressive character of the disease are against thrombosis or hemorrhage as the etiologic agent, although either of these, if present in the upper cervical spinal cord or lower end of the medulla oblongata, might give rise to symptoms such as the patient presents. Tumor in this region should also be considered. The fact that there is no disturbance of sensation, however, militates against this diagnosis. In spite of the patient's age there is no reason to forego the amount of information obtainable from examination of the spinal fluid. Pressure studies and estimation of the protein content of the fluid might lead to a more positive diagnosis. If there is a hydrodynamic block in the spinal fluid, or if the protein is markedly elevated, tumor is likely and competent neurologic or neurosurgical advice should be sought.

2. So far as can be ascertained, there is no poisonous substance in the "bootjacks" from palmetto trees or in the muck which lies under them. Toxic neuritis, therefore, from these substances has not been reported. It is more likely that the patient suffers from one of the more ordinary types of infectious neuritis and that he should be treated along the usual lines for this disease. Such treatment consists in massage and galvanism to the muscles affected, if these muscles do not respond to the faradic current, and prevention of overstretching by the use of splints, if necessary. If there are obvious foci of infection elsewhere in the body, these should be removed. Antineuritic vitamin B might be added to the diet if the neuritis is at all extensive.

HYPOSPADIAS IN ADULT

To the Editor:—Please give me information on operations for hypospadias in adults. A man aged 30 has had some childhood diseases, an attack of influenza in 1919 and two attacks of gonorrhea. His physical examination is essentially negative except for a slight secondary anemia (color index 0.9) and a penile hypospadias. The urinary meatus is approximately 1½ inches back from the end of the penis. There is a definite chordee and a rudimentary urethral groove with a rudimentary corpus cavernosum reaching nearly to the end of the penis. There is a large dorsal prepuce in the shape of an apron. My plan of operation is to straighten out the penis by a transverse ventral incision with subsequent severing of the rudimentary cavernosum and suturing in the opposite direction. In the second step for building up the urethra proper I want to use the Ombredanne method, utilizing the prepuce. I wish to know your opinion as to this plan and I would like to know further whether the use of a permanent catheter during the first or second stage of the operation, or during both stages, is indicated. Is it advisable to destroy the hair follicles in case some hair bearing part of skin is used for building up the new urethra? There are plenty of references to be found as to the correction of this malformation in early childhood, but so far I have been unable to find anything dealing with the situation in adults.

M. D., California.

ANSWER.—Whether or not a man who is 30 years of age should have an operation for the correction of hypospadias may be open to debate. This depends on whether the patient is married; if he is, and can perform his marital duties, it might be well at 30 to "let well enough alone." On the other hand, if the patient is not married and wishes his defect corrected before he gets married, one might discuss the question of an operation for the hypospadias.

If the presence of the chordee prevents the patient from having satisfactory intercourse, one is justified in advising him to have the curvature straightened. As suggested, this may be done by making a transverse ventral incision. On the other hand, a good many men are now using the tube graft instead of the procedure suggested in the query. If the patient is married and his wife has borne children, it may be possible that correcting the deformity alone is all that may be needed. But if it is a question of sterility and if the external urethral orifice is far back, the urethra of course would have to be advanced in order to deposit the semen in the vagina. Then again, if the opening is only an inch or so behind the tip of the glans penis it might be well to leave it alone.

The objection to the use of the Ombrédanne method is the fact that hair may be present and stone formation may occur; therefore many men believe in the advisability of destroying the hair follicles.

Various types of operations are discussed and illustrated in textbooks on urology.

PERFORATION AND BLEEDING IN PEPTIC ULCER

To the Editor:—I would appreciate it if you would give me some information regarding an accident case under my care. 1. I should like to know the percentage of occurrence of perforation in ulcer ventriculi et duodeni according to the latest statistics. 2. What is the percentage of occurrence of bleeding in cases of ulcer of the stomach and duodenum? 3. What is the percentage of occurrence of the two in the same ulcer patient? 4. From what literature could I learn most about occurrence of bleeding in ulcer cases after trauma (heavy lifting and strenuous work)?

M. D., Massachusetts.

ANSWER.—A critical review of the recent literature on the incidence of perforation and bleeding in chronic gastric and duodenal ulcer reveals a variable array of statistics. This is particularly true with reference to bleeding. Statistics based on the cases admitted to the large metropolitan charity hospital or outpatient clinic differ materially from those published by the private hospital or private practitioner. There also is marked variation in the immediate mortality from bleeding ulcer following medical or surgical treatment. The incidence of acute and chronic perforation and hemorrhage is also influenced by the element of time; that is, the duration of the disease when the patient first came under observation and the duration of the period of observation thereafter. Therefore the data submitted are approximate, strictly speaking, rather than exact.

1. Acute perforation occurs in 5 per cent of ulcers of the stomach and duodenum. Statistics embracing a large series of surgically verified cases reveal that subacute (forme fruste) and chronic perforation occurs in from 25 to 28 per cent of both gastric and duodenal ulcers. The large majority of these (over 90 per cent) are of the chronic variety.

2. The percentage of occurrence of bleeding in both gastric and duodenal ulcer is 30.

3. The occurrence of both acute perforation and hemorrhage is infrequent. Available statistics are too meager on which to base any definite conclusions. Goldman (*Ann. Surg.* **40**: 541 [June] 1938) reported seven cases of this nature representing 2 per cent of the entire series reported. The impression that bleeding ulcers do not perforate and perforating ulcers do not bleed is justifiable to a considerable extent. However, as high as 8 per cent of duodenal ulcers which had given rise to hemorrhage of variable extent showed evidence of chronic perforation at operation.

4. The following textbooks and articles may be consulted:

Brahdy, Leopold, and Kahn, Samuel: Trauma and Disease, Philadelphia, Lea & Febiger, 1937, p. 181.

Custerman, G. B., and Balfour, D. C. The Stomach and Duodenum, Philadelphia and London, W. B. Saunders Company, 1936, p. 756.

Crohn, B. B. Affections of the Stomach, Philadelphia, W. B. Saunders Company, 1927, p. 621.

Beams, A. J. Industrial Aspects, *Ohio State M. J.* **32**: 130 (Feb.) 1936.

Alvarez, W. C.: Severe Gastric Hemorrhage Produced by Violent Abdominal Massage, THE JOURNAL, July 11, 1936, p. 129.

On the basis of repeated observation by competent authorities with large experience, the evidence seems indisputable that unusual physical or mental exertion as well as alcoholic debauches and external trauma can provoke gross hemorrhage in a patient harboring an acute or chronic peptic ulcer.

POSTOPERATIVE DEATH FROM ANURIA

To the Editor:—In a case of anuria following an operation for gangrenous appendicitis, death resulted forty-three hours after operation without indications of peritonitis, and with the patient in what seemed to be a good condition when he left the operating room. The patient, aged 37, weighed 175 pounds (79 Kg.), was the father of three healthy children and enjoyed good health until the operation except for two previous spells of abdominal pain that were suggestive of appendicitis, the first in 1936 and the second in July 1938. He was seen forty-eight hours after the first symptoms, November 9. Operation began at 7:05 p. m. and terminated at 8:50. A much thickened gangrenous appendix was removed and rubber drains were inserted down to the stump. He left the operating room with a pulse rate of 100, respirations 30, blood pressure 164 systolic, 64 diastolic. Before operation he had a red blood cell count of 5,180,000 with hemoglobin 100 per cent, white cell count 13,800, polymorphonuclears 86 per cent and with a urine specific gravity of 1.020 and negative for albumin, sugar, acetone, indican, red or white cells, casts, crystals or amorphous sediment. The Wassermann reaction was negative. After operation his condition seemed good. He had a morphine injection of one fourth grain (0.16 Gm.) at midnight and 4 a. m., with 2,000 cc. of 10 per cent dextrose in saline solution given during the night. He voided 10 ounces (300 cc.) of urine at 6 a. m., at which time the pulse was 98, respirations 22 and temperature 101. During the day of November 10 hypodermoclysis of 3,000 cc. of 10 per cent dextrose solution was given. The abdomen remained soft but the temperature went up to 103 F. and no urine was voided until death occurred at 3 a. m. November 11. The catheter was passed three times during this period but no urine was found in the bladder. The patient died in coma. Stimulants, oxygen and general symptomatic treatment were given. Did this anuria result from operative shock, the anesthetic (nitrous oxide and ether), by reflex action on a normal kidney or were we dealing with a previously damaged kidney that was functioning well? Was forty-three hours sufficient time for a fatal uremia in a previously normal person?

C. E. JUMPER, M. D., El Paso, Texas.

ANSWER.—In this case there was probably a previously damaged kidney. The damage had not been sufficient, however, to cause symptoms or produce albumin in the urine. Nonprotein nitrogen and urea estimation before the operation would have been of value and interest but certainly was not indicated in the emergency that existed. It would seem unlikely that nitrous oxide and ether or operative shock could have been an important factor in this case. An intravenous injection of 50 per cent dextrose solution might have been of some value, although it is doubtful.

CRYSTALLIZED BLOOD FOR DIAGNOSIS

To the Editor:—I am writing with regard to the article published in *Life* magazine January 2 on "Diseases Diagnosed by Crystallized Blood." I am much interested in this article and should like to know where I can obtain more detailed information concerning the subject.

PAUL G. WEISMAN, M. D., Colfax, Wash.

ANSWER.—The article in question was probably based on a report by Dr. P. Bégouin of Bordeaux at the June 28, 1938, meeting of the Académie de médecine of Paris. According to this report, blood for the test is obtained by needle puncture of the fingers and is received in distilled water to which a solution of chloride of copper is added. Crystallization takes place in the specimen in eighteen hours. The results were as follows: In cancer a correct diagnosis was made in thirty of seventy-nine cases of various types and in tuberculosis a correct diagnosis in eight of nine cases; in one patient who had syphilis and a cancer of the tongue, the former was diagnosed but not the latter; crystallization permitted a differential diagnosis to be made between a cancer of the epithelial type and other tumors such as sarcoma and those of a mixed cell type. It has been maintained by Pfeiffer, a Swiss chemist, who is the originator

of the test, that this method is also helpful in determination of the correct drug to be employed. It seems to be agreed that long training is required before one can attempt this method. The only one who has apparently tried the method so far is the French surgeon Dr. Bégouin and so far as can be determined he has not made any further observations since early in 1938. It is at least obvious from the foregoing that this method is highly experimental, that it will require much independent confirmatory evidence before it can be accepted and that it should under no circumstances replace the more established and definitely known reliable methods of diagnosis and treatment already available. This is another example of premature (to say the least) publicity in a nonmedical publication.

GOLD INJECTIONS AND COLITIS

To the Editor:—A young woman has been having gold injections for lupus erythematosus. During the process of treatment some tenesmus with frequency of bowel movements developed. At this time a maculopapular rash was noted on the chest and abdomen. The diarrhea insidiously progressed within the next two weeks into a fulminant colitis. Rectal discharges became frequent, bloody and purulent. On repeated cultures of the stools the predominant organism was identified as the diplostreptococcus described by Bargen. The heavy metals are notably eliminated in the intestinal tract. In overdoses (or susceptibility?) thrombosis of the small blood vessels of the intestinal mucosa occurs. Bargen has described the histologic appearance of ulcerative colitis as essentially a process of minute and discrete ulceration attendant on septic infarction of the blood vessels of the mucosa and submucosa of the colon. Whether Bargen is right in his contention that this organism is the causative agent of ulcerative colitis or whether, as Paulson has pointed out, this is one of a group of cocci whose normal habitat is in the ileum and which have been washed down into the colon is beside the point in this instance. Is it plausible to feel in this case that the resistance of the intestinal wall may have been lowered as a result of damage to the endothelium of the blood vessels in the excretion of the injected gold so that usually innocuous bacterial inhabitants have become facultative pathogens? Or is it safe to dismiss the sequence of heavy metal administration and diarrhea as purely coincidental and unrelated?

M.D., Connecticut.

ANSWER.—No references have been found in the literature to reactions from gold injections in which there was a complicating involvement of the mucous membrane of the colon. The patient did have a maculopapular eruption, however, over the chest and abdomen, and it would certainly be wise to discontinue further gold injections. It might be well to use bismuth injections instead. Before instituting that form of treatment, however, the blood should be examined carefully. With all of the heavy metals, it is well known that occasionally aplastic anemia and even agranulocytosis occurs. Is there a possibility of such a contingency in this case? If there is, one could understand the reaction in the colon, as there is no reason why such a reaction could not occur there just as well as in the pharyngeal space, for example.

HORSE DANDER AND HORSEHAIR IN ALLERGY

To the Editor:—I should like to call your attention to an apparent discrepancy between an answer under the subject "Asthma" in THE JOURNAL Nov. 12, 1938, and that under the subject "Allergy to Horsehair" in THE JOURNAL March 12, 1938. In the later answer it is stated that "even patients sensitive to horse dander are not sensitive to horsehair after its preparation for use in furniture." The answer on March 12 says that "therefore horsehair mattresses can cause symptoms in all but the least sensitive individuals." Does this difference exist between those who have asthma and those who have a vasomotor rhinitis or do the two answers represent individual opinions?

GORDON B. SMITH, M.D., Rutland, Vt.

ANSWER.—The inquiry resolves itself into a question of whether an individual who is sensitive to horse dander usually has a sensitivity to horsehair as found in mattresses and furniture or whether such an individual is never sensitive to horsehair. Several years ago, with the idea of attempting to solve this question, some experiments were made on horse dander sensitive individuals. Varying dilutions of extracts of horse dander, unwashed horsehair and horsehair after it had been prepared for use in mattresses were injected and the reactions noted. In one such instance the horse dander reacted with a dilution of 1 : 10,000,000 or higher. The unwashed hair gave its first reaction in 1 : 10,000 dilution and the washed hair in 1 : 100. In another highly sensitive individual the 1 : 10,000,000 gave a 3+ reaction, while the first doubtful reaction with the unwashed hair was with 1 : 1,000 and the extract of washed hair did not react in the strength of 1 : 50. This would indicate that by far the greatest amount of antigen is removed by the process of cleaning, washing and boiling. The washed hair contains less than $\frac{1}{10,000}$th part of the antigen. However, the fact remains that some horse dander antigen can be demonstrated and it is possible that some horse dander sensitive individuals will have trouble from horsehair as it is found in mattresses.

The practical application of these facts is that a large source of exposure such as a hair mattress should not be inflicted on a horse dander sensitive person, whether he has asthma or vasomotor rhinitis. It is questionable, however, whether a small amount of horsehair such as is found in the seats of chairs or in the padding of coats would be of any particular importance.

THERAPY OF STILL'S DISEASE

To the Editor:—A girl aged 9 years has been suffering from Still's disease for the last three or four years. She has had her tonsils and bad teeth out without any improvement and has been receiving a vaccine—I think Crowe's vaccine—at the hands of another physician. This little girl is becoming deformed and progressively worse. Is there anything which has been found useful in checking the progress of this disease?

M.D., Ontario.

ANSWER.—The following might be suggested as regards treatment:

1. A high caloric, high vitamin diet.
2. Bed rest.
3. Cevitamic acid, 25 mg. a day.
4. Crystalline vitamin B_1, 1 mg. a day.
5. Ten thousand units of vitamin D, each day.

Every effort should be made to prevent further deformities and to correct those already present. This can be accomplished only by means of physical therapy, exercises, and whatever conservative orthopedic measures such as the application of casts and the like are necessary.

Still's disease is at times unrelenting in its progress, despite all forms of therapy. This, however, is the exception rather than the rule. Occasionally one sees striking results from repeated small transfusions. A good conservative, supportive regimen aimed at maintaining as much joint motion as possible, plus the prevention and correction of deformities, should be carried out indefinitely and should never be abandoned even when any of the so-called specific measures are being employed.

TRAUMA AND THROMBOSIS

To the Editor:—A man aged 52 sustained a fracture of the right ascending ramus of the pelvis on Aug. 20, 1938. October 12 he was taken with distress in his chest and shortness of breath without actual pain. October 15 he began to cough, had a fever and developed a bronchial pneumonia. He recovered from the pneumonia after three weeks and on November 9 was taken with a pain in his right leg and the leg became swollen and somewhat discolored. He had a slight fever for ten days. A diagnosis of phlebitis was made. The heart shows some myocardial damage. It was impossible to tell whether the myocardial damage was of recent origin or of old standing. I should like to know how long after an injury it is possible to get a thrombus from the injury. Also can you mention some authorities or literature on this subject. In this case it was nearly three months from the time of the injury to the phlebitis. Could the pneumonia have been due to an infarct? Any information you can give on these subjects will be appreciated.

M.D., New York.

ANSWER.—A pelvic thrombosis following fracture of the pelvis is not infrequent; it may occur a few days after the injury but remain a short "silent" clot in the hypogastric vein without clinical manifestations. Such clots are more apt to give rise to pulmonary emboli than those in the external iliac or femoral veins. Later such clots in the pelvis may extend to the common or external iliac veins and give rise to a typical deep thrombophlebitis.

It is not stated in the query whether or not the patient was steadily immobilized from the time of the injury to the time of the symptoms in the chest; it is possible that this was an infarct, followed by consolidation, but the data supplied do not permit any opinion as to the cause of the bronchopneumonia. Sudden dyspnea with some cyanosis, lobar involvement followed by pleuritic rub, rusty sputum, and the x-ray finding of a triangular infarct with increased hilus shadows on the side of involvement are suggestive of a pulmonary embolus.

The time interval between trauma and thrombosis varies from a few days to several months. If the patient is immobilized as a result of the injury, small initial clots may grow by apposition until some mechanical, physiochemical or climatic stress suddenly makes the process manifest. The longest recorded interval between injury and embolism is the case of Strauss: a man aged 49 died of pulmonary embolism three months after fracturing his patella; eighteen days before death, however, a light embolic shower occurred.

DILATION OF CERVIX AND STERILITY

To the Editor:—I have a patient who is anxious to have a baby. She is 30 years old and has been married six years. The family history, menstrual history and physical examination are essentially negative except for a mild case of malarial fever and pyelitis several years ago. A specialist who saw her stated that the mouth of the cervix was too small or closed and that if she had this dilated she would probably become pregnant. Since the menstrual history is essentially negative, I could not understand the rationale of this treatment. Will you please explain? It seems to me that the thing to do in this case would be to make a thorough study of the endocrine system and examine a specimen of semen from the male.

M.D., South Carolina.

ANSWER.—In a case in which menstrual blood can pass downward through the cervical canal there is obviously no anatomic barrier to the upward passage of spermatozoa. Two conditions not infrequently associated with stenosis of the external os require consideration when the complaint is sterility. Of these the first is retention and inspissation of the endocervical mucus, which may form a plug viscous enough to entangle the male cells. The second is female genital hypoplasia, of which a long, conical and anteflexed cervix with a pin-hole os is a familiar stigma. For the latter disorder dilation would be entirely useless. The presence or absence of the first abnormality can be determined precisely by direct observation of the endocervical secretions and by postcoital examination. If it is found to be present, repeated gentle dilations may produce some benefit; but more permanent results are obtained by a small posterior median discision. Otherwise dilation, though a time-honored procedure, has no value. The endocrine balance of the wife should certainly be investigated. It is of primary importance in all cases of sterility to evaluate the husband's semen according to the most critical mathematical standards before subjecting the wife to any elaborate treatment.

AZOOSPERMIA AFTER MUMPS ORCHITIS

To the Editor:—A man of 38 has azoospermia. At the age of 18 years he had bilateral mumps orchitis. It is not known whether he had spermatozoa before that or not. The testes now are about 40 per cent of usual size and apparently of normal consistency. He has developed normally otherwise. The growth of hair on the face is not heavy and there is not much hair on the body. The voice is normal. Sexual desire and ability are quite normal. The blood pressure is 95-100 systolic, 60 diastolic. The pulse at rest is 60, the temperature a little subnormal, the basal metabolism minus 10 per cent. The red cell count is normal, the white count low normal with mild eosinophilia at times. The patient is quite intelligent. He states that he tires easily on mental exertion and has difficulty in concentration. He is inclined to yawn more than normal. His general physical condition is fairly good and he stands physical exertion quite well. Do you believe that the use of anterior pituitary-like substance or testosterone or both would be of value? Have you any other suggestions as to treatment?

M.D., New York.

ANSWER.—At the present time it is not likely that spermatogenesis could be produced in this patient by the administration of the anterior pituitary-like principle from the urine of pregnant women or testosterone. Further observations of the basal metabolic rate should be made, because the level of metabolism is of much more importance than a single test. If the level should prove to be below minus 15 per cent, it should be raised to normal with desiccated thyroid.

SULFANILAMIDE FOR GONORRHEA: DOSAGE IN CHILDREN

To the Editor:—What is the dosage and what are the contraindications for sulfanilamide (oral and parenteral) in the adult in acute and chronic gonorrheal urethritis? Could this drug be given safely to infants and children? If so, in what dosage? What tests should be done in order to find out the tolerance of an office patient to sulfanilamide?

M.D., California.

ANSWER.—The systems of dosage employed by various urologists when sulfanilamide is used in the treatment of gonococcic infections vary somewhat. Probably the most commonly used system for ambulant patients consists of giving from 4 to 5 Gm. of sulfanilamide for two days, from 3 to 4 Gm. a day for five days and then from 2 to 2.5 Gm. a day for a week; this to be followed by 1.3 Gm. a day for two weeks, making the total course of treatment about one month.

The only real contraindication to the use of sulfanilamide is that the patient has previously been given the drug and has had a toxic reaction to the drug. To such a patient a test dose of 0.3 Gm. should be given and the patient kept under observation for possible immediate toxic reaction.

Sulfanilamide may be given with as much safety to infants and children as to adults. Because of a greater fluid intake, children require slightly larger doses of sulfanilamide than do adults. In children severely ill with an infection which may be treated with sulfanilamide the total dose the first day is based on 0.15 Gm. of the drug per pound of body weight. This is divided into six parts and is given at intervals of four hours. In children less severely ill the daily dose is based on 0.07 Gm. per pound of body weight and likewise split into six parts and given at four hour intervals.

Sodium bicarbonate may generally be administered concurrently with sulfanilamide. There is no test for susceptibility to the drug except the administration of a small test dose by mouth.

ASTHMA FROM CONJUGAL ASSOCIATION

To the Editor:—A man aged 32, a miller in a feed mill, has asthmatic attacks. These attacks come on only at night and when his wife is in the house. Previous to meeting his wife before marriage nine years ago the patient never had an attack. He has had complete physical examinations, negative Wassermann tests and forty-two negative pollen and food diagnostic tests. It appears that when his wife is away from home any length of time the attacks cease, but when she returns the attacks return. Being near other women does not bring on any attacks. The patient's wife has tried eliminating all forms of cosmetics and certain types of clothing for several months at a time, with no particular effects. She does not use waveset in her hair or any other form of preparations, such as dye. The patient's occupation does not seem to have any bearing on his case, because, as stated, he does not have any when his wife is away. *His attacks are of the severe asthmatic type, which require epinephrine for* relief, and this he must take nightly if his wife is at home. For a few years it has been impossible for them to sleep in the same bed at night. It has been suggested that the wife's hair might be the offending cause. Is this likely? A pharmaceutical house wants a pound of hair in order to make a vaccine for treatment. What would be the best procedure to determine the exciting cause of the attacks?

M.D., Pennsylvania.

ANSWER.—The evidence given would certainly seem to incriminate something associated with the wife. Assuming that this information is correct and that no factors other than the wife's surroundings play a part, the obvious thing is to have the wife avoid completely those materials which might possibly bring on asthma in her husband.

First of all, she should use nothing but hypo-allergenic cosmetics. She should especially avoid perfumes during the day as well as during the night. It would also be wise for both husband and wife to use plain soap instead of perfumed soap. By this method one should be able to rule out sensitivity to orris root. Incidentally, the patient himself should use no talcum powder or after-shave lotion except one made by those concerns making nonallergic preparations. It is also possible that the patient is sensitive to silk, and it would be well for the wife to substitute for silk nightgowns either cotton or linen.

Another possibility is that the husband might be sensitive to some contraceptive used by the wife such as a solution or a jelly of some sort. The use of such a preparation should be stopped for a trial. Of paramount importance is the necessity of complete testing of the skin. The query states that only forty-two pollen and food tests were carried out. This is by no means complete, as there are several hundred tests including such substances as feathers, animal danders, silk, kapok, furs, molds and yeasts, and house dust.

Lastly, the patient's occupation might lead to asthmatic attacks. However, it is hard to believe this important, as the attacks come on only at night and only when the wife is in the house.

CONGENITAL AMBLYOPIA

To the Editor:—Please give me some information on congenital amblyopia. What is the consensus as to classification as a functional or organic condition?

M.D., South Dakota.

ANSWER.—Ophthalmologic opinion is still greatly divided as to whether congenital amblyopia is a functional affair or whether it is due to some anatomic failure of development. Thus far no eye with clinically proved congenital amblyopia has ever received microscopic examination, but there seems to be clinical evidence that some cases are organic while others are purely functional. In the higher degrees of congenital amblyopia in which the vision is somewhere between 1/200 and 10/200, central visual acuity can never be developed to a higher degree, indicating an organic malformation as yet undetected. In the second type of case the central vision will vary between 2/200 and 0.2 and it can be improved considerably by continuous occlusion of the fellow eye. In the third type of case the vision will be between 0.2 and 0.6 and it can always be brought up to practically normal if the developmental work is started early enough in life. The latter two types would seem to be more functional than organic.

HEREDITY OF HEMOLYTIC JAUNDICE

To the Editor:—I should appreciate some information on the hereditary factor in hemolytic jaundice. A woman of 19 had her spleen removed with this diagnosis eight years ago. Her mother and two maternal aunts had splenectomies with the same diagnosis. She knows of no other cases in her family history on either side. She now comes asking the question "If I had children is it probable that some of them would have this disease?"

M.D., Massachusetts.

ANSWER.—Hemolytic jaundice seems to be inherited as a "dominant" mendelian character (Campbell, J. M. H., and Warner, E. C.: *Quart. J. Med.* **19**:333 [April] 1926). A dominant mendelian character is inherited directly from parent to child. Of the children half, on the average, will have the character and half will not. The former will again behave like their parents; the latter, provided they marry a normal person, which is almost certain to be the case with such a rare condition, will have normal children. Males and females are affected equally and are equally able to transmit the defect.

Occasionally jaundice is present from birth in a patient whose family history is negative. Such a case probably represents a curious mutation from the ordinary constitution of the family, but the disease will be transmitted as a dominant mendelian character as described (Cyclopedia of Medicine **7**: 593, 1934). The abnormal fragility of the red cells found in hemolytic jaundice may occur in latent cases without the other signs and symptoms of hemolytic jaundice, and it may persist after splenectomy.

LATE ANEMIA NOT RELATED TO SULFANILAMIDE

To the Editor:—In August 1938 I gave a 16 year old boy, living 15 miles out of town, at least 125 grains (8 Gm.) and no more than 150 grains (10 Gm.) of sulfanilamide over a period of four or five days for sore throat. Since he is the son of a telephone operator I heard from him frequently; he became quite cyanotic according to his mother's report and on the second or third night woke up with a "spell" lasting less than an hour, which I thought was a "nightmare" as a result of the gastric irritation. At intervals of two or three days for three or four weeks I had reports that the boy was normal. About the twenty-fifth of this month the boy seemed below par, and his mother took him to a local physician, who found a slight anemia (4 million plus); this physician is wondering whether the anemia might be the result of the action of the sulfanilamide given six months ago. The boy has seemed normal since, and I wish to know whether anemia often if ever lasts six months except following violent reactions.

J. D. MICHIE, M.D., Childress, Texas.

ANSWER.—There is little reason to suspect that an anemia noted six months after a course of sulfanilamide is the result of the patient having taken the drug. The anemias resulting from sulfanilamide therapy are generally acute or subacute hemolytic anemias, which clear up rapidly after the drug is stopped.

X-RAYS AND SCABIES

To the Editor:—How effective are the x-rays in the treatment of scabies? How many units may be used safely, how often repeated, and at what intervals? Do the mercurials, zinc and other metals in ointments or lotions interfere with the use of x-rays? In the case in question the outbreak has been confined to the back of the hand. Various ointments have caused the eruption to abate even to the point of apparent cure, but new outbreaks occur at intervals of two and three weeks. Gloves have been dry cleaned and boiled and bedding also. The history of the case is diagnostic of scabies and the burrows are typical.

M.D., Illinois.

ANSWER.—Given enough x-rays the itch mite and her eggs would be destroyed, but the skin of the patient would also suffer. Scabies requires treatment of the whole skin except that of the head; therefore x-rays are not adapted to its treatment, even though they are known to be effective. Scabies can be eradicated by much simpler means.

Yes, heavy metals and their salts impede the passage of x-rays, depending on the density of the metal, the amount overlying the skin and the character of the rays.

CORNEAL GRAFTING

To the Editor:—Would you outline the indications and contraindications along with the technic of corneal grafting after the methods of Castroviejo and the Russian procedure?

M.D., Pennsylvania.

ANSWER.—The indication for corneal grafting, regardless of the method used, is the presence of an opaque cornea that prohibits the adequate passage of light. The contraindications are somewhat more important and are based on experience. First is a corneal staphyloma, either with or without increased intra-ocular pressure; second, a chronic incurable infection of the tear passages, conjunctiva or cornea; third, calcareous deposits within the cornea; fourth, increased intra-ocular pressure, and fifth, lack of proper light perception. It is fairly well known that the cornea scarred by burns, particularly chemical burns, does not accept a transplant favorably, whereas a corneal transplantation is almost always successful in cases of old interstitial keratitis. There are various gradations between these two extremes.

Description of the Castroviejo and of the Filatov technic is too lengthy for these columns. Briefly, Castroviejo transplants a rectangle of cornea which has been removed by the twin knives that he designed, while Filatov transplants a round button of cornea which has been removed by a rotary trephine. Both surgeons are varying their technic continuously as experience improves their methods and technicians improve their instruments. Much remains to be done, but the results in the hands of these experts are encouraging.

ARGYRIA AND ANTISYPHILITIC TREATMENT

To the Editor:—A syphilitic woman used a mouth wash of strong solution of silver nitrate (lunar caustic sticks dissolved in warm water) for ulcers on her tongue in April 1938. She now shows a dark blue coloring of the skin of her entire body, which is slowly fading. What antisyphilitic treatment is contraindicated and what would be permissible and why?

D. T. COLE, M.D., Anna, Ill.

ANSWER.—There is no contraindication to antisyphilitic treatment in a case of argyria. The silver in the tissues is inert and difficult to affect by any kind of treatment. The claim has been made that argyria has improved after long continued ingestion of iodides but this has not been substantiated (Yandell, L. P.: Cyanosis from Nitrate of Silver Removed by Iodide of Potassium, *Am. Practitioner* **5**:329, 1872). Yandell's patient was given mercury vapor baths before the iodide was used. This is the only evidence that silver once deposited in the tissues is affected by antisyphilitic treatment. Others have tried it and reported no success.

In the case under discussion the syphilis should be treated without regard for the argyria.

TUBERCULOSIS AND ALUMINUM PAINT

To the Editor:—A man aged 24, working in a factory for the last three years spraying aluminum paint, contracted tuberculosis of the lungs. X-ray examination shows tuberculosis of the lungs and no silicosis. He wishes to collect compensation. How can we prove that his work was the cause of his tuberculosis?

M.D., Massachusetts.

ANSWER.—Proof of occupational origin of tuberculosis is rarely possible except in cases in which opportunities for contact with the tubercle bacillus are unusual; for example, nurses in tuberculosis hospitals. Excessive mortality from tuberculosis in any occupational group constitutes presumptive evidence of environmental factors that may depress natural resistance and permit new or preexisting foci of latent infection to cause active clinical disease. Preemployment examinations to prove the absence of such disease before exposure are essential; periodic examinations during exposure must demonstrate its evolution. Extra-occupational contacts with an "open" carrier must be excluded. Evidence is not available of high tuberculosis rate in aluminum spray painters.

VIABILITY OF TUBERCLE BACILLI ON PIPES—FORMALDEHYDE STERILIZATION

To the Editor:—I have been asked by a pipe lover who was bequeathed a fine collection of pipes, including both clay and wood bowls, five years ago by a tuberculous patient whether it would now be safe to smoke the pipes and if not whether there is any available procedure which will make the pipes safe and still not damage their smoking qualities or appearance.

M.D., California.

ANSWER.—Under the conditions mentioned there is no evidence to support the belief that tubercle bacilli would remain viable after five years. Experimental evidence has shown that tubercle bacilli die within sixty to ninety days under conditions in which they cannot metabolize. However, in order to make absolutely certain that no infection can be transmitted the pipes can be safely sterilized without damage to them in formaldehyde fumes.

INTRAVENOUS MEDICATION FOR PYELITIS

To the Editor:—What preparation is used for pyelitis intravenously?

J. LOUIS WALDNER, M.D., Loveland, Colo.

ANSWER.—A 40 per cent solution of methenamine in 5 cc. ampules is obtainable for intravenous administration. Prontosil (the disodium salt of 4-sulfamido-phenol-2'-azo-7'-acetylamino-1'-hydroxynaphthalene-3',6' disulfonic acid) is given intravenously. A 2.5 per cent solution is put up in ampules of 5 cc. Neoarsphenamine is given intravenously in a dose of 0.2 Gm. for coccic infections.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, April 15, page 1529.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, May 1-2 (Part II only—limited to a few centers), June 19-21, and Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Oral* examinations for all candidates, St. Louis, May 13-14. *Written.* Various places throughout the United States, Sept. 9. Applications must be filed by July 11. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Philadelphia, Oct. 30-Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral, clinical and pathological examinations for all candidates, Part II examinations (Groups A and B) will be held in St. Louis, May 15-16. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* Various cities throughout the country, Aug. 5. *Oral.* St. Louis, May 15 and Chicago, Oct. 7. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: St. Louis, May. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: St. Louis, May 12-13 and Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Cincinnati, Nov. 15. Appointments must be made before July 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Chicago, May 13. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: St. Louis, May 11-14. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Part II.* New York, May 8 and May 9. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: White Sulphur Springs, W. Va., May 26-28. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

New York September Examination

Mr. Herbert J. Hamilton, chief, Bureau of Professional Examinations, reports the written examination held at Albany, Buffalo, New York and Syracuse, Sept. 19-22, 1938. The examination covered nine subjects. An average of 75 per cent was required to pass. Three hundred and fifty-nine candidates were examined, 221 of whom passed and 138 failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Arkansas School of Medicine		(1938)	1
Georgetown University School of Medicine	(1937, 5),	(1938, 3)	8
Loyola University School of Medicine		(1938, 2)	2
Northwestern University Medical School	(1936),	(1938)	2
Rush Medical College	(1937, 4),	(1938)	5
School of Med. of the Division of Biological Sciences		(1934)	1
University of Illinois College of Medicine		(1933)	1
University of Kansas School of Medicine		(1935)	1
University of Louisville School of Medicine		(1938)	1
Johns Hopkins University School of Medicine		(1936)	1
Boston University School of Medicine		(1937)	1
Harvard University Medical School	(1937),	(1938)	2
Tufts College Medical School	(1922),	(1934), (1937)	3
University of Michigan Medical School	(1935),	(1937), (1938)	3
St. Louis University School of Medicine		(1935)	1
Columbia Univ. College of Physicians and Surgeons		(1938, 5)	5
Long Island College of Medicine	(1936),	(1937, 2)	3
New York Medical College and Flower Hospital		(1938, 2)	2
New York University College of Medicine	(1934),	(1936), (1937, 4), (1938, 7)	13
Syracuse University College of Medicine		(1938, 3)	3
University of Buffalo School of Medicine		(1938, 3)	3
University of Rochester School of Medicine		(1934)	1
University of Oregon Medical School		(1936)	1
Hahnemann Medical College and Hospital of Philadelphia		(1937), (1938)	2
Jefferson Medical College of Philadelphia		(1937), (1938)	2
Temple University School of Medicine		(1936), (1938)	2
University of Pennsylvania School of Medicine		(1937)	1

District of Columbia Reciprocity and Endorsement Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports twenty-three physicians licensed by reciprocity and one physician licensed by endorsement from Sept. 15 through Dec. 14, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine	(1934)		Maryland
Georgetown University School of Medicine	(1933), (1934)		Maryland
Howard University College of Medicine	(1931) (1932) Georgia, (1936) Maryland		Penna.,
Emory University School of Medicine	(1922), (1934), (1935)		Georgia
University of Kansas School of Medicine	(1936)		Kansas
Johns Hopkins University School of Medicine	(1936)		Maryland
St. Louis University School of Medicine	(1903)		Missouri
Columbia Univ. College of Physicians and Surgeons	(1922), (1911)		New York
Long Island College Hospital	(1935)		New York
Western Reserve University School of Medicine	(1935)		Ohio
Hahnemann Med. College and Hospital of Philadelphia	(1934)		Maryland
University of Pennsylvania School of Medicine	(1925)		Penna.
Woman's Medical College of Pennsylvania	(1934)		Penna.
University of Tennessee College of Medicine	(1926)		Tennessee
Medical College of Virginia	(1936)		Penna.
Univ. of Virginia Department of Medicine	(1932), (1936)		Virginia

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Virginia Department of Medicine	(1911)		U. S. Navy

Idaho October Examination

Hon. J. L. Balderston, former commissioner of law enforcement, reports the written examination held by the Idaho State Medical Examining Board, Oct. 3-5, 1938. The examination covered twenty-three subjects and included 160 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists		(1937)	76
University of Colorado School of Medicine		(1937)	79
George Washington University School of Medicine		(1938)	78
Northwestern University Medical School		(1935)	83
Rush Medical College	(1936) 78,	(1937)	83
University of Michigan Medical School		(1936)	75
Washington University School of Medicine		(1937)	78
University of Nebraska College of Medicine		(1937)	79
Univ. of Oregon Medical School	(1917) 83, (1936) 85,	(1937)	82
University of Texas School of Medicine		(1937)	81
McGill University Faculty of Medicine		(1935)	75
Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau		(1935)	

Louisiana December Report

Dr. Roy B. Harrison, secretary, Louisiana State Board of Medical Examiners, reports the written examination held in New Orleans, Dec. 1-3, 1938. The examination covered twelve subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-nine candidates were examined, all of whom passed. Fourteen physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine	(1938)	81.2,	83.9
University of Southern California School of Medicine	(1938)		86.4
Howard University College of Medicine	(1937)		82.2
Emory University School of Medicine	(1936)	82.5, (1938)	85.2
Loyola University School of Medicine	(1937)		82.2*
Northwestern University Medical School	(1938)		82.3
Indiana University School of Medicine	(1937)		83.1
Louisiana State University Medical Center	(1938)	85.3,*	87.4*
Tulane University of Louisiana School of Medicine	(1937)		83.1, 86.6, (1938) 78.9, 79.7, 82.7, 85.2†
University of Maryland School of Medicine and College of Physicians and Surgeons	(1938)	81.8,	84.2
University of Minnesota Medical School	(1938)		83.3*
New York University College of Medicine	(1938)		84.9
University of Oklahoma School of Medicine	(1938)		86.7
University of Cincinnati College of Medicine	(1938)		84*
University of Oregon Medical School	(1938)		85.4
Medical College of the State of South Carolina	(1938)		83.5
Baylor University College of Medicine	(1938)		79.4
University of Virginia Department of Medicine	(1938)		83.3
University of Wisconsin Medical School	(1938)		85.1
Queen's University Faculty of Medicine	(1930)		78.1†

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine	(1937)		Arkansas
Rush Medical College	(1901)		Illinois
Tulane University of Louisiana School of Medicine	(1935)		S. Carolina
University of Michigan Medical School	(1930)		Michigan
University of Minnesota Medical School	(1935)		Minnesota
University of Nebraska College of Medicine	(1933)		Nebraska
Meharry Medical College	(1928)		Tennessee
University of Tennessee College of Medicine	(1932), (1936)		Tennessee
Vanderbilt University School of Medicine	(1935)		Mississippi
Baylor University College of Medicine	(1936)		Texas
Medical College of Virginia	(1931)		Virginia
University College of Medicine, Virginia	(1912)		Virginia
University of Wisconsin Medical School	(1937)		Kansas

* This applicant has completed the medical course and will receive the M.D. degree on completion of internship. License has not been issued.

† Granted a Temporary Permit. License withheld pending completion of United States citizenship.

Wisconsin September Reciprocity Report

Dr. Henry J. Gramling, secretary, Wisconsin State Board of Medical Examiners, reports five physicians licensed by reciprocity at the meeting held in Milwaukee, Sept. 14, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Illinois College of Medicine	(1937)		Illinois
University of Minnesota Medical School	(1931)		Minnesota
Washington University School of Medicine	(1935)		California
University of Nebraska College of Medicine	(1931)		Nebraska
Marquette University School of Medicine	(1936)		Montana

National Board of Medical Examiners

The National Board of Medical Examiners reports that its certificate was awarded to eighty-seven applicants who were successful in the examinations in part III held in the fall of 1938. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical [illegible]	(1937), (1938, 5)		6

Ohio May-June Examination

Dr. H. M. Platter, secretary, Ohio State Medical Board, reports the oral, written and practical examination held at Columbus, May 31-June 3, 1938. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Three hundred and five candidates were examined, 297 of whom passed and eight failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Med[illegible]	(1937)		82.1
Loyola Univers[illegible]			*
Northwestern [illegible]	(1938) 81.7, 86.9, 87.8		81.5,
Rush Medical College	(1937) 81.8,	(1938) 83.5,	87.7
School of Medicine of the Division of Biological Sciences	(1937)		88.1
University of Illinois College of Medicine	(1938)		86.9
University of Minnesota Medical School	(1932), 87.2, (1933)		88.5
Creighton University School of [illegible]			81.6
University of Rochester School [illegible]	82.8, 82.9, 84.2, 85.6, 87.4, 87.8		80.6,
Eclectic Medical College, Cincinnati	(1938)		80.2, 81.3, 81.5, 82.3, 82.3, 83.2, 83.3, 83.4, 83.6, 83.9, 84, 84.2, 84.3, 84.3, 84.4, 84.6, 84.8, 85.1, 85.2, 85.3, 85.5, 85.6, 86.8, 86.8, 87.1, 87.2, 87.2, 87.3, 87.6, 88.1, 88.4, 89.7
Ohio State University College of Medicine	(1938)		79.4, 79.7, 79.8, 80.3, 80.4, 80.5, 80.5, 80.7, 80.8, 81, 81.1, 81.3, 81.4, 81.5, 81.6, 81.7, 81.8, 81.9, 82.1, 82.1, 82.2, 82.2, 82.2, 82.3, 82.4, 82.4, 82.4, 82.4, 82.5, 82.8, 82.9, 83.1, 83.1, 83.1, 83.2, 83.4, 83.4, 83.4, 83.5, 83.5, 83.6, 83.6, 83.6, 83.6, 83.7, 83.7, 83.8, 83.8, 83.9, 83.9, 83.9, 83.9, 84, 84.1, 84.2, 84.3, 84.5, 84.6, 84.7, 84.7, 84.7, 84.8, 84.8, 84.9, 84.9, 85.1, 85.2, 85.2, 85.3, 85.4, 85.5, 85.8, 85.9, 85.9, 85.9, 86.1, 86.3, 86.4, 86.5, 86.5, 86.7, 86.8, 86.9, 87.2, 87.3, 87.3, 87.4, 87.7, 87.8, 88.1, 90.3
University of Cincinnati College of Medicine	(1938)†		80.3, 80.6, 80.6, 80.9, 81, 81.2, 81.3, 81.4, 81.4, 81.9, 81.9, 81.9, 82, 82, 82.1, 82.4, 82.6, 82.7, 83.1, 83.2, 83.2, 83.3, 83.4, 83.4, 83.4, 83.5, 83.6, 83.7, 84, 84, 84, 84, 84, 84.1, 84.1, 84.1, 84.1, 84.2, 84.2, 84.2, 84.3, 84.6, 84.6, 84.8, 85, 85.1, 85.2, 85.3, 85.3, 85.4, 85.4, 85.5, 85.7, 85.8, 85.8, 85.9, 86, 86.1, 86.2, 86.2, 86.3, 87.3, 87.4, 87.9, 88.5, 88.7

Book Notices

The Relation Between Injury and Disease. By Jewett V. Reed, B.S., M.D., F.A.C.S., Assistant Professor of Surgery, Indiana University, Indianapolis, and Charles P. Emerson, A.B., M.D., D.Sc., Research Professor of Medicine, Indiana University. Collaborating: E. B. Mumford, B.S., M.D., F.A.C.S., Consultant U. S. Veterans Bureau Hospital. Cloth. Price, $7.50. Pp. 577, with 21 illustrations. Indianapolis: Bobbs-Merrill Company, 1938.

A new and strange pseudopathology has been slowly evolving in the courts, based on so-called expert medical testimony, especially in connection with diseases of industrial workers, alleged to be the result of injury. This strange pseudopathology will become more and more unscientific unless physicians in court become more determined to substitute propter hoc reasoning for the post hoc arguments which in many cases determine decisions. Physicians in cases of injury in which there is an element of liability recognize that many of the settlements made are unfair if judged on their scientific merits although just in view of the medical testimony presented to the court. Many injured persons receive little or nothing for physical disabilities justly compensable, while others receive awards for diseases not due to injury. The purpose of this book is to reduce the number of such injustices. It is designed to be helpful especially to (1) lawyers who present accident cases before courts and boards, (2) officials of insurance companies which carry casualty risks and (3) physicians and surgeons. It is based on the authors' thirty-six years of experience. Their discussions are limited to well recognized diseases; in some injury may be a primary etiologic factor, in others it never is and in still others it may modify the course. In the study of cases in which trauma and disease are assumed to be associated the physician should critically scrutinize the history of the accident and separate the actual facts of the injury from the statements given by the patient. He should also have personal knowledge of all the features of the patient's disease and be accurately informed as to all the factors which could possibly have entered into its cause.

Nouvelle pratique dermatologique. Publiée par MM. Darier, Sabouraud, Gougerot, Millian, Pautrier, Ravaut, Sézary, Clément Simon. Secrétaire Général: Clément Simon. Tome VIII. Dermatologie topographique; thérapeutique; médecine légale; table alphabétique. Par MM. P. Blum et al. Half-Cloth. Price, 300 francs. Pp. 867, with 178 illustrations. Paris: Masson & Cie, 1936.

The first 380 pages of volume VIII, which brings to a close this huge work, are devoted to topographic dermatology. This is of great value to the general practitioner but of much less value to the specialist in that it is largely repetitious. It is interesting, however, owing to the fact that it is the first contribution of its kind since the work of Sabouraud, which appeared in 1905 and which was translated into several languages.

Sabouraud and Pignot in fifty-two pages cover the semeiology of the scalp. About the same number of pages are taken up by Bory on the topographic dermatology of the face and nose. The illustrations in this article are numerous and excellent. Fernet follows with about eighty pages on the lips, mouth and tongue. This constitutes a valuable contribution to the volume and, although the illustrations are not as numerous as in the preceding article, they are in sufficient number and of the highest quality. A short paper by Montlaur on the topographic dermatology of the large folds is thorough and of much value even to the specialist. Thorel contributes a short article on the male external genitalia and Bralez does the same on the female external genitalia. The illustrations in both are all that could be desired. Gonin gives a few paragraphs to each of the many conditions affecting the anal region. Burnier makes the most of the pages allotted him to list and describe the disorders of the hands and feet. Payenneville describes the dermatoses of the mammae, and Blum those of the umbilicus.

The second half of the volume is devoted to therapeutics, plastic surgery and medicolegal dermatology with an introduction by Darier. Fernet discusses the general hygiene of the skin and scalp. This is followed by forty-four pages on general therapy by Darier and Dreyfus. Included are such subjects as internal treatment of cutaneous accidents, treatment of the cutaneous sensitization by hemotherapy and serotherapy, peptone therapy, lactotherapy, urinotherapy and the use of the "substance P" of Oriel, heat therapy, vaccinotherapy and chemotherapy. Under the last heading the drugs used in dermatology are listed alphabetically and discussed in detail. The various regimens are then taken up, acid and alkaline regimens, the methods of modifying the metabolism of the skin, modification of the vitamin equilibrium, uric acid, the fats and the proteins. Glandular therapy is thoroughly covered, after which the chapter is ended with several pages devoted to treatment of the central nervous system.

Fernet and Heurre contribute an exhaustive article of forty pages to internal treatment of the dermatoses, sixteen pages to pharmaceuticals and forty-two pages to external treatment.

The physical agents used in dermatology are discussed and evaluated by Girondeau. The author describes the indications for and the technic of the use of the douche filiforme, hot air, actinotherapy, infra-red high frequency currents, the diathermic or electric bistoury, the galvanic current, electrolysis, ionization and electrical baths.

Cottenot covers, as well as any one could in forty-three pages, the technic and the results of the use of the roentgen ray and radium in dermatology. Solente describes the preparation of carbon dioxide snow and the technic of its application to lesions of the skin. Although many dermatologists hesitate to treat epitheliomas with the snow, the author does not hesitate to use it in selected cases and finds the results superior to those of any other method.

Ravaut has thoroughly covered the field of electrocoagulation in forty pages. There are many illustrations showing the marvelous results it is possible to attain with this method. The pictures of the epitheliomas of the face and the left hand and of the melanomas of the face and the foot are particularly impressive.

An excellent chapter on plastic surgery is contributed by Dufourmentel. The technic for face lifting and for correction of various deformities of the face is set forth in much detail and illustrated with line drawings. A most interesting part of the chapter is the method of correcting ptosis of the mammae. The illustrations shown before and after treatment would seem to indicate conclusively that the technic is highly successful in such cases.

The volume closes with a chapter on medicolegal dermatology by Vivatte and Sidi. Obviously this chapter, which is thorough, is primarily for the French and has little to offer to dermatologists of other countries.

An excellent index of sixty-eight pages is appended.

Giants of Medicine in Pioneer Kentucky: A Study of Influences for Greatness. By William Allen Pusey, A.M., M.D., LL.D. [Reprinted from February 1938 issue of Medical Life.] Boards. Pp. 35-64. New York: Froben Press, 1938.

Having been reared in Kentucky and having personal knowledge of its geography, its people and its resources, William Allen Pusey is in the fortunate position of being able to portray the courage, resourcefulness, vision and ability of its pioneers and with a facile pen to pay tribute to their attainments. This he has interestingly and adequately done. The circumstances under which these pioneers lived and worked, including a lack of hospitals, of trained nursing personnel, of a knowledge of surgical cleanliness, of instruments of precision as we now know them, of the aid of the blessed insensibility of anesthesia and the presence of inherent and seemingly insuperable difficulties, make the incredulity of their contemporaries readily understandable and emphasize their claims to renown for the development of greatness. Bardstown, with the most illustrious courts and bar in the West, had but 820 inhabitants when Brashear did the first hip joint amputation in 1806. Danville, with McDowell's home under the shadow of the state capitol, had but 432 inhabitants in 1809, when he did his first ovariotomy, and but 804 at the time of his death in 1830. Lexington, the Athens of the West, then as now a remarkable town in a wonderful country, had but 1,795 inhabitants at the time of the establishment of the medical school, Transylvania University, in 1799, and but 6,997 when Dudley was at the zenith of his career. In his study of the influences for greatness to be found in a then virgin country, inhabited by hostile savages and the beasts of the forest, Dr. Pusey gives due credit to the type of people who settled this frontier, well equipped physically, mentally and socially for the struggle of the survival of the fittest. They

were well endowed with those qualities for which Americans are noted the world over, independence of thought, enthusiasm of purpose, courage to undertake and patience to carry through: in the words of Dr. Pusey "a vigorous breed of men trained to its highest efficiency by the exactions of frontier life." Written in beautiful clear language, this history of medical pioneers proves an entrancing one.

Der Magenkrebs. Von Dr. med. Georg Ernst Konjetzny, o. ö. Professor der Chirurgie der Hansischen Universität, Hamburg. Cloth. Pp. 289, with 155 illustrations. Stuttgart: Ferdinand Enke, 1938.

Konjetzny, one of the foremost authorities on the subject, summarizes thirty years of study of the problem of gastric carcinoma. He reaffirms the views previously published, coordinates the data, adds much new material and presents a complete picture of our present knowledge of the genesis of gastric carcinoma and its clinical application. In the introduction he calls attention to the well known fact that the stomach is the organ most frequently affected by carcinoma and that today the majority of patients so afflicted come to the internist and the surgeon too late for cure. In the battle against gastric carcinoma only two possibilities exist: prophylaxis or early radical surgical treatment. Under the heading of etiology Konjetzny discusses first the rôle of heredity and concludes that cancer as such is not inherited, only a certain tendency or organ disposition. External conditions are thought to be the more important factors. The theory of contagiousness and infectivity seems disproved, as does the Cohnheim concept of carcinoma arising from embryonal cells left over after the development of the fetus and its organs. Trauma is considered significant only as it relates to the sequelae of corrosion of the mucosa, as in acid or alkali poisoning. Virchow's theory of carcinoma as a resultant of local disease processes is accepted, and a large section of the monograph is devoted to the thesis that "the chronic inflammatory conditions which demand greatest consideration as the basis of gastric carcinoma formation are the chronic gastritis with its sequelae and the chronic gastric ulcer."

Konjetzny's life work indeed has been the study of the relationship between chronic gastritis, benign ulcer and carcinoma. He views gastritis as the basis for both ulcer and carcinoma. In his experience gastric carcinoma is always associated with a pronounced chronic atrophic or atrophic-hyperplastic gastritis. Carcinoma never develops in a normal gastric mucosa. The essential process in the gastritis-carcinoma relationship is not the inflammation but regenerative changes in the epithelium constantly induced by it. The complete transition from pure gastritic changes to polyp formation and carcinoma is described in detail and well documented with convincing illustrations. The carcinomatous development begins in the cells over a broad area of the mucosa and hence is multicentric in origin. The subject of carcinomatous transformation of a benign ulcer is discussed at length. The conclusion is reached that it is not possible by clinical methods alone to make such a diagnosis. Pathologic evidence, especially the histologic, is more definite, but here also difficulties exist. The diagnosis cannot be made on the basis of any single pathognomonic finding but rather by a careful analysis of all the evidence. Carcinoma may develop in the edge of a benign ulcer or adjacent to the ulcer but independent of it, related not to the ulcer but to the gastritis, to which Konjetzny attributes both the ulcer and the carcinoma. With regard to the differentiation of ulcer-gastritis and carcinoma-gastritis Konjetzny says that in ulcer the gastritis is usually more acute and is localized to the antrum whereas in carcinoma the gastritis tends to be more chronic and to involve larger areas of the gastric mucosa. There is, however, no specific or fundamental difference.

Among the macroscopic forms of carcinoma Konjetzny distinguishes (1) the pronounced mushroom or polypoid tumor, which develops chiefly in the lumen of the stomach, (2) the ulcerated dishlike growth with clearly defined borders, (3) the ulcerated carcinoma without a definite wall or a sharp border and with infiltration of the gastric wall beyond the edge of the ulcer and (4) the definitely diffuse type in which the borders of the tumor are not palpable, usually beginning in the antrum, and consisting particularly of the so-called linitis plastica and carcinoma fibrosum. The microscopic types are variable and are not to be correlated with the macroscopic. The prognosis for surgical treatment is, on the whole, much better in the first and second groups than it is in the third and fourth. A histologic classification is not of much prognostic value.

Effective therapy depends first on early examination and second on gastric resection of all early carcinomas and indeed of all cases of polypoid gastritis, this being definitely a precarcinomatous, if not already carcinomatous, condition. All patients with digestive symptoms should report promptly to the physician, who should use all available diagnostic means necessary for the establishment of a definite diagnosis. The history, physical examination and gastric analysis are not sufficient but should be combined with a search for occult blood in the stool and with careful roentgenologic and gastroscopic examination. These methods are most valuable. The author is opposed to exploratory laparotomy as a diagnostic procedure because the methods mentioned are reliable and also because small carcinomas often cannot be palpated even when the surgeon has the stomach in his hands. When a portion of the stomach is held in suspicion clinically, it should be resected. Resection should be carried out in almost all cases of carcinoma even though a very radical operation is required, such as complete gastrectomy or partial gastrectomy combined with partial colectomy. The chief contraindications to resection are definite, proved distant metastases or extensive carcinomatous peritonitis. Significant palliative effects have been obtained even when Krukenberg tumors had to be removed in addition to the gastric lesion. In spite of the fact that Hitzenberger and Merkler found thirteen year cures in only 2 per cent of 272 patients with gastric carcinoma, Konjetzny feels that undue pessimism is not warranted even in the young. The longest cure observed in the Breslau clinic was that of a man operated on when 31 years old and was known to be well twenty-one years later. With earlier diagnosis and earlier radical resection, better results should be obtained.

Essentials of Medicine. By Charles Phillips Emerson, M.D., Research Professor of Medicine, Indiana University, Indianapolis, and Nellie Gates Brown, R.N., Director of Training School for Nurses, Ball Memorial Hospital, Muncie, Indiana. Thirteenth edition. Cloth. Price $3. Pp. 845, with 164 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1938.

The evolution of this volume through thirteen editions since 1908 has been an account of medical and nursing school programs during the last thirty years. Originally intended as a primer for the medical student's study of disease, the book at present is chiefly in the hands of the student nurse. The authors in preparing this edition have patterned it on the unit plan, following suggestions in the curriculum guide for schools of nursing. A section of doubtful value is the one intended to encompass the field of public health and medical sociology, an impossible task in five pages. Furthermore, with the mention of a drug such as sulfanilamide, the failure to list and discuss the toxic signs and symptoms is a real error, especially at a time when all are interested in this new drug and its dangers. The student nurse here has presented for her the essentials of medicine in a concise yet readable 1, 2, 3 form. The volume should continue to be one of the most popular in the series of nursing manuals.

Malaria in the Netherlands. By N. H. Swellengrebel and A. de Buck. Cloth. Price, 5 florins. Pp. 267, with 25 illustrations including 2 plates. Amsterdam: Scheltema & Holkema, Ltd., 1938.

The authors, both from the Institute of Tropical Hygiene of Amsterdam, have presented an interesting book on an old but ever changing and expanding theme. One might think that such a subject would be dry and uninteresting, but this book is presented in such a way that it easily holds the attention. The authors have done a perfectly tremendous amount of careful and continued investigation, and one must be impressed by the enormous amount of difficult work involved in gathering the data presented.

It is something of a surprise to know that the Netherlands presents such a serious malarial problem. It lies far to the north and even though it is low and full of canals, one would naturally think of malaria as only an occasional importation

as it is in most of our northern latitudes. But the authors show that special development and adaptation of a short-winged anopheles mosquito is such that the malarial parasites remain active after the sexual activities have subsided and that the mosquitoes are able to convey infections actively until December, by remaining constantly in the homes of the inhabitants and more or less regularly feeding on them. Even though thousands are diverted into stables and feed on live stock there are so many mosquitoes that most houses contain some, hidden away in dark recesses, where they are not easily found. The number seems to be in direct relation to the efficiency of the housekeeper.

Some progress has been made in malaria control, but the authors show how many difficult problems are involved, healthy carriers being being one of the most difficult. Each new addition of territory reclaimed from the sea adds a new focus. It appears that the ditches draining the land are the source of most of the mosquito breeding. The short-winged variety breeds best in water of rather high salinity, while the long-winged anopheles, also abundant, breeds in fresh water but appears not to be a vector of any importance. The authors conclude that satisfactory control will come only at a later time when the canals are so diluted with fresh water that the short winged vectors will be largely eliminated.

A final and instructive chapter is included on the treatment of dementia paralytica with malaria and a description of the careful control exercised, as well as the valuable studies made on the life cycle of malarial parasites in these carefully controlled observations. The material is convincing and will be of value to any one engaged in public health work, but it is by no means limited to this field. Every doctor who comes in contact with malaria will profit by its perusal.

Pathological Technique: A Practical Manual for Workers in Pathological Histology Including Directions for the Performance of Autopsies and for Microphotography. By Frank Burr Mallory, A.M., M.D., Sc.D., Consulting Pathologist to the Boston City Hospital, Boston, Mass. Cloth. Price, $4.50. Pp. 434, with 11 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

Little fault can be found with this small work on the methods for staining and handling tissues removed from the body for further study. Everything in the book has been accepted as proper technic in most of the country's major laboratories. This is merely intended to be a compend of accepted practical technics and as such is little concerned with theory or complicated methods. The results to be expected from each stain are listed at the end of each description of method. The descriptions are highly practical, are listed in outline form and are sufficiently complete. The portion on rapid frozen section technic is too brief, since such cursory dismissal does not permit description of modern technic highly useful to the surgical pathologist. However, this volume seems aimed at the postmortem laboratory and as such a fairly complete treatise on necropsy procedure is presented. There are some tables and a brief section on photography, the latter being useless to the professional and a bit too difficult and brief for the amateur. Illustrations are few, an omission painfully noticeable in a laboratory manual. This brief volume describes most of the stains necessary for use in a well equipped laboratory and would make a valuable addition to a pathologist's library.

Die Ernährung der olympischen Kämpfer in Vergangenheit und Gegenwart. Von Adolf Bickel, Professor der pathologischen Physiologie an der Friedrich-Wilhelms-Universität, Berlin. Bücher der Hygiene und Volksernährung, Band III. Herausgegeben von Dr. Max Winckel. Paper. Price, 1 mark. Pp. 36. Berlin: Deutsche Verlagsgesellschaft m. b. H., 1938.

This little book is a lecture delivered by the author on invitation to the Academy of Medicine of Athens, Greece. It is a relatively popular application of part of the thesis of his longer book, The Relation of the Quality of Protein to the Process of Assimilation, published in Basle by Benno Schwabe & Co. in 1938. The book is of primary interest to general physiologists, nutritionists, team physicians and those interested in research in the physiology of exercise. It is of general interest to the sportsman physician. The author has investigated sources, including Gardiner's Greek Athletic Sports and Festivals, for information concerning the type of diet used by the athletes of the ancient Olympic period. He has compared the ancient diet with that of various groups of participants in the 1936 Olympics at Berlin. In view of his observation that the diet consisted primarily of animal and vegetable protein in both groups, the paper inquires into the possible reasons for this emphasis. The work of Zuntz, Loewi, Mueller and Caspari in 1906 indicated that alpine climbers with "arbeits hypertrophie" established indulged their heavy activity using a diet relatively free from protein and composed mostly of the so-called energy foods with no noticeable detrimental physical effects. Attempt is made to rationalize the high protein diet, postulated as the athlete's instinctive choice, on the basis of the increase in oxidation accompanying high protein intake and the rallying of glycogen from known and possibly unproved sources to meet the strain of heavy athletic training and competition. Consideration by tables is given the relative value and oxidizing influence of some forty forms of protein, as well as their possible effects on glycogen availability and storage.

A Text-Book of Dental Histology and Embryology Including Laboratory Directions. By Frederick Bogue Noyes, B.A., D.D.S., Sc.D. Fifth edition revised by Isaac Schour, B.S., D.D.S., M.S., Professor of Histology and Head of Department, University of Illinois College of Dentistry, and Harold Judd Noyes, B.S., D.D.S., M.D. Cloth. Price, $6.50. Pp. 415, with 281 illustrations and 15 plates. Philadelphia: Lea & Febiger, 1938.

For twenty-five years this eminently practical textbook has served as an introduction to dental training, covering as it does a much wider field than the title indicates. This edition reflects the newer ideals and standards of scientific dentistry. When one considers the chapters on the postnatal development of the head, the lymphatic system and tooth eruption and the discussions of comparative and experimental anatomy, the book is really a work on the biology of the teeth. The developing tooth, with its rapid, regular growth and its immediate response to certain changes in the blood, is becoming a veritable growth kymograph, and this type of book commands a general scientific audience (even though the chapter on operative dentistry is likely to set the layman's teeth on edge). Dr. Schour has reorganized the material and has added much that is new. Pathologic conditions, especially caries, are included, as well as normal structure, but the emphasis is kept on the physiologic interpretation of minute structure. The introductory chapters on embryology are followed by descriptions of the histogenesis and definitive structure of the various dental tissues. Here the "histophysiologic remarks" are provocative and stimulating. Thus (p. 113) one reads: "Enamel automatically records in its structure its own stages of formation and calcification as well as its response to systemic disturbances. These records remain permanent after the enamel has completed its formation and calcification and has lost the kymographic properties of its growing period." The new chapter on gums and gingivae is excellent. There are an appended laboratory outline and a good index.

Beitrag zur Kenntnis sklerosierender Entmarkungsprozesse im Gehirn mit besonderer Berücksichtigung der diffusen Sklerose (Strümpell-Heubner): Eine klinisch-anatomische Studie. Von Lárus Einarson, Professor anatomiae an der Universitat Aarhus, und Axel V. Neel, Privatdozent Psych. Laboratorium d. Universitat Kopenhagen. Acta Jutlandica Aarsskrift for Aarhus Universitet X,2. Paper. Price, 7 kroner. Pp. 160, with 72 illustrations. Copenhagen: Einar Munksgaard, Leipzig: Georg Thieme, 1938.

This monograph is based on a careful clinical and microscopic study of six new cases of demyelinizing lesions of the brain. In four of these cases the condition belonged to the class of the Strumpell-Heubner diffuse scleroses and in the other two it was difficult to classify. On the basis of this study the authors come to a new classification of the demyelinizing diseases and attempt to interpret cases reported in the literature in the light of their new conception. They distinguish five types: (1) the blastomatous reactive form, (2) the exogenous inflammatory form, (3) the nonfamilial degenerative form, (4) the heredodegenerative familial form and (5) the peculiar concentric sclerosis of Balo. They propose as a generic term for all these lesions "leukoencephalopathia scleroticans diffusa." Their classification is based on the microscopic appearances, and they believe that with all these lesions many and varied etiologic factors play a part simultaneously. The monograph is well illustrated and has an extensive bibliography. It will be useful to any neuropathologist interested in this interesting group of pathologic conditions.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Use of Drugs or Operative Surgery by Osteopath Unlawful.—Frankowsky, an osteopath, was licensed in Illinois to treat human ailments without the use of drugs or operative surgery. He was convicted of practicing medicine by the use of drugs, medicines or operative surgery and appealed to the Supreme Court of Illinois.

The medical practice act of Illinois provides for the issuance of three kinds of licenses: (1) to practice medicine in all its branches; (2) to treat human ailments without the use of drugs or medicines and without operative surgery, and (3) to practice midwifery. Frankowsky contended that the act was unconstitutional because its classification of practitioners was false, arbitrary, discriminatory and unscientific. He further argued that the practice of osteopathy includes the use of operative surgery, antiseptics and anesthetics but that, under the act, he could not be licensed to practice osteopathy according to its tenets, including surgery, unless he also studied the use of drugs and medicines in which he did not believe. But, the Supreme Court pointed out, the constitutionality of the medical practice act had been repeatedly upheld. In *People* v. *Witte*, 315 Ill. 282, 146 N. E. 178, 37 A. L. R. 672, the court specifically upheld the reasonableness of the division of all practitioners who seek to cure human maladies into two classes, one class consisting of those having the right to practice medicine in all its branches, including operative surgery, and the other class consisting of those who seek to treat human ailments without the use of medicines or operative surgery. Such a classification is based on a difference in attainments and not on any named method or school of healing. The legislature was not bound to enact a statute which provided for the licensing of applicants from the various schools of healing by creating a separate class for each school with distinct qualifications. The limitations laid down in the statute are voluntary; if an applicant who believes in curing human ailments without the use of drugs or surgery desires to use either, he may qualify himself by meeting the requirements of the statute for a license to practice medicine in all its branches. Frankowsky's contention that he was discriminated against because, in order to practice surgery, the act required him to take instruction in the use of drugs and medicines when he did not believe in their use was answered in the Witte case as follows:

> The practice of surgery requires the use of antiseptics, anaesthetics, and other drugs and medicines. Hence the Legislature required instruction in drugs and medicines as a necessary qualification to enable a physician to perform a surgical operation. In its judgment, no person ought to be permitted to practice surgery without showing a knowledge of drugs and medicines.

Because in the judgment of the Supreme Court no new ground of attack on the constitutionality of the medical practice act had been made, it refused to assume jurisdiction in the case and transferred it to the appellate court of Illinois, first district, second division. In a memorandum decision, the appellate court affirmed the judgment of conviction.—*People v. Frankowsky (Ill.), 13 N. E. (2) 178; 15 N. E. (2d) 894.*

Medical Practice Acts: Chiropractic as the Practice of Medicine.—Three chiropractors were convicted of violating the medical practice act of Texas. They appealed to the court of criminal appeals, which in each case held that the complaint was sufficient and that the evidence justified the judgment of conviction.

In the Hoy case, the defendant was charged with maintaining an office where he offered to treat human beings for diseases and disorders; that he held himself out as capable of effecting a cure thereof without having first registered a license to practice medicine in the office of the clerk of the district court, as required by law, and that on a certain day he treated a named person for a disease and disorder and charged money therefor. At the trial, the patient named in the information testified that he consulted the defendant relative to a physical or nervous ailment, that the defendant, after informing him that he had "misplacements of the vertebrae," gave him no medicine or performed no surgical operation but undertook manually to adjust his vertebrae, and that he paid the defendant $50 for a series of such adjustments. It was further shown that Hoy had not registered any license in the office of the district clerk. The defendant complained that the trial court erred in refusing to sustain challenges for cause which he had interposed with respect to certain jurors who had served previously on juries which had convicted defendants charged with violating the medical practice act. If it had been shown to the trial court, said the appellate court, that the facts in the present case were the same as or similar to those adduced on the trial of the preceding cases, then the challenge for cause should have been sustained. In the absence of any such showing, the trial court correctly overruled the challenge, the challenged jurors having stated that their prior jury service would not affect their opinion or conclusion in the pending case, that they knew none of the facts in the case and that they were not prejudiced against the defendant.

In the Ehrke case, the evidence showed that the defendant maintained an office where he pursued his occupation as a chiropractor and that on a certain day he treated a named patient for nervousness for which he received compensation and that he had not registered a license in the office of the clerk of the district court. An indictment or information, said the court of criminal appeals, for practicing medicine without a license is sufficient if it substantially follows the language of the statute. Furthermore, it is well settled that chiropractors who make adjustments for compensation come within the purview of the medical practice act and must comply with the requirements of that act in order to be entitled to practice.

In the Lanford case, the defendant admitted that he had lived in Brownwood for six years and had been a chiropractor all that time. The evidence showed that he visited a named patient and gave him "a little adjustment and rubbed his jaw —and the back of his neck." The defendant admitted making the visit and that he received $2 as a fee. This evidence was held sufficient to sustain the conviction.

Having found no error in the records, the judgments of conviction were affirmed.—*Hoy v. State (Texas), 115 S. W. (2d) 629; Ehrke v. State (Texas), 115 S. W. (2d) 631; Lanford v. State (Texas), 115 S. W. (2d) 632.*

Workmen's Compensation Acts: Cecitis and Appendicitis Attributed to Trauma.—The deceased was a woman aged 19 who had apparently been in good health. On April 20, in the course of her employment, she slipped, it was claimed, from a stool on which she was standing and struck her right side against the sharp edge of a metal table. No one saw her fall, but within ten or fifteen minutes after the alleged injury she informed a fellow worker that she had been injured in the manner stated, and during that interval a Mr. Crowley saw her sitting on a stool with her hand pressed tightly against her right side. When she reached home shortly afterward her mother observed a swollen and bruised area on her right side. The published report does not make clear what her condition was between that time and May 9, on which day her appendix was removed. At the operation the cecum and the appendix were found inflamed, but there was no perforation. Peritonitis and pneumonia developed and death followed May 15. The claimant, the guardian of the minor child of the deceased, claimed compensation under the Michigan workmen's compensation act. The department of labor and industry awarded compensation. The employer and its insurance carrier appealed to the Supreme Court of Michigan.

Basing its finding solely on the testimony of the physician who performed the appendectomy, the department of labor and industry held in effect that the accidental injury complained of was the proximate cause of death in that it aggravated or produced the appendicitis and that the peritonitis and pneumonia that caused death resulted from the operation to remove the appendix. It would be difficult to determine, the physician had testified, whether the inflammation and infection of the cecum

and appendix were "due to injury or due to some other inflammation," but in his opinion the cecum became infected because the devitalization of the tissue by the trauma enabled infection to set in more easily. He testified further that the probabilities of the cecum becoming infected to the extent that it was from anything other than injury were very slight; that the infection spread from the cecum to the appendix because inflammation in the cecum tends to travel downward, and as the cecum is a blind pouch the "pus or infection" tends to accumulate there and pass on down into the appendix, and that the immediate cause of the death of the deceased was the peritonitis and pneumonia that resulted from the infection and inflammation. Under the circumstances, the Supreme Court could not agree with the contention of the employer and its insurer that the testimony of this physician was incompetent and inadmissible, because his conclusions were based on facts which were not supported by the evidence and because, while it was permissible for him to express an opinion, it was not permissible for him to give his conclusions. The court pointed out that, although the witness did announce his conclusions, he also expressed his opinion that the injury was the cause of the condition which he found.

The finding of the department of labor and industry, said the Supreme Court, that the deceased had sustained an accidental injury arising out of and in the course of her employment was supported by sufficient evidence. The testimony of her fellow worker as to what the deceased told her concerning the injury was admissible as a part of the res gestae and so came within an exception to the rule that hearsay evidence is inadmissible. Furthermore, the statement of the deceased as to her injury was substantiated by the testimony of her mother and of Mr. Crowley as to what they observed shortly after the injury.

The award in favor of the claimant was affirmed.—*Froman v. Banquet Barbecue, Inc. (Mich.), 278 N. W. 758.*

COMING MEETINGS

American Medical Association, St. Louis, May 15-19. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

American Academy of Tuberculosis Physicians, St. Louis, May 13-14. Dr. Arnold Minnig, 638 Metropolitan Bldg., Denver, Secretary.

American Association for the Study of Goiter, Cincinnati, May 22-24. Dr. W. Blair Mosser, 133 Biddle St., Kane, Pa., Secretary.

American Association for Traumatic Surgery, Hot Springs, Va., May 8-9. Dr. Ralph G. Carothers, 409 Broadway, Cincinnati, Secretary.

American Association of Genito-Urinary Surgeons, Williamsburg, Va., May 24-26. Dr. Charles C. Higgins, 2050 East 93d St., Cleveland, Secretary.

American Association of Industrial Physicians and Surgeons, Cleveland, June 5-8. Dr. V. S. Cheney, Armour and Company, Union Stock Yards, Chicago, Secretary.

American Association of the History of Medicine, Atlantic City, N. J., April 30-May 1. Dr. Henry E. Sigerist, 1900 Monument St., Baltimore, Secretary.

American Association on Mental Deficiency, Chicago, May 3-6. Dr. E. Arthur Whitney, Washington Road, Elwyn, Pa., Secretary.

American Bronchoscopic Society, Rye, N. Y., May 26. Dr. Lyman Richards, 319 Longwood Ave., Boston, Secretary.

American Dermatological Association, Montebello, Canada, May 31-June 3. Dr. Fred D. Weidman, University of Pennsylvania Medical Laboratories, Philadelphia, Secretary.

American Gastro-Enterological Association, Atlantic City, N. J., May 1-2. Dr. Russell S. Boles, 1901 Walnut St., Philadelphia, Secretary.

American Gynecological Society, White Sulphur Springs, W. Va., May 22-24. Dr. Richard W. TeLinde, 11 East Chase St., Baltimore, Secretary.

American Heart Association, St. Louis, May 12-13. Dr. Howard B. Sprague, 50 West 50th St., New York, Secretary.

American Laryngological Association, Rye, N. Y., May 24-26. Dr. James A. Babbitt, 1912 Spruce St., Philadelphia, Secretary.

American Laryngological, Rhinological and Otological Society, Chicago, May 10-11. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Medico-Legal Association, Chicago, May 12-13. Dr. Michel Pijoan, 124 Commonwealth Ave., Boston, Secretary.

American Neurological Association, Atlantic City, N. J., June 5-7. Dr. Henry A. Riley, 117 East 72d St., New York, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Eugene M. Blake, 303 Whitney Ave., New Haven, Conn., Secretary.

American Orthopedic Association, Buffalo, N. Y., June 5-8. Dr. Ralph K. Ghormley, 110 Second Ave. S.W., Rochester, Minn., Secretary.

[illegible] Society, New York, May 22-23. Dr. Thomas J. [illegible] 40th St., New York, Secretary.

[illegible] Society, Sky Top, Pa., Apr. 27-29. Dr. Hugh Culloch, 325 North Euclid Ave., St. Louis, Secretary.

American Physiological Society, Toronto, Canada, Apr. 26-29. Dr. A. C. Ivy, 303 East Chicago Ave., Chicago, Secretary.

American Psychiatric Association, Chicago, May 8-12. Dr. Arthur H. Ruggles, Butler Hospital, Providence, R. I., Secretary.

American Radium Society, St. Louis, May 15-16. Dr. Frederick W. O'Brien, 465 Beacon St., Boston, Secretary.

American Rheumatism Association, St. Louis, May 15. Dr. Loring T. Swaim, 372 Marlborough St., Boston, Secretary.

American Society for Clinical Investigation, Atlantic City, N. J., May 1. Dr. Isaac Starr, University of Pennsylvania Hospital, Philadelphia, Secretary.

American Society for Experimental Pathology, Toronto, Canada, April 26-29. Dr. Paul R. Cannon, Dept. of Pathology, University of Chicago, Chicago, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Toronto, Canada, Apr. 26-29. Dr. G. Philip Grabfield, 319 Longwood Ave., Boston, Secretary.

American Society for the Study of Allergy, St. Louis, May 15-16. Dr. J. Harvey Black, 1405 Medical Arts Bldg., Dallas, Texas, Secretary.

American Society of Biological Chemists, Toronto, Canada, Apr. 26-29. Dr. C. G. King, Univ. of Pittsburgh, Dept. of Chemistry, Pittsburgh, Secretary.

American Society of Clinical Pathologists, St. Louis, May 12-14. Dr. Alfred S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Surgical Association, Hot Springs, Va., May 11-13. Dr. Charles G. Mixter, 319 Longwood Ave., Boston, Secretary.

American Therapeutic Society, St. Louis, May 12-13. Dr. Joseph F. Elward, 1726 Eye St. N.W., Washington, D. C., Secretary.

American Urological Association, White Sulphur Springs, W. Va., May 29-June 1. Dr. Clyde L. Deming, 789 Howard Ave., New Haven, Conn., Secretary.

Arkansas Medical Society, Hot Springs National Park, May 8-10. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Associated Anesthetists of the United States and Canada, St. Louis, May 15. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary General.

Association for the Study of Internal Secretions, St. Louis, May 13-14. Dr. E. Kost Shelton, 921 Westwood Blvd., Los Angeles, Secretary.

Association of American Physicians, Atlantic City, N. J., May 2-3. Dr. Hugh J. Morgan, Vanderbilt University Hospital, Nashville, Tenn., Secretary.

Association of Military Surgeons of the United States, Washington, D. C., May 8-10. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.

California Medical Association, Del Monte, May 1-4. Dr. George H. Kress, 450 Sutter St., San Francisco, Secretary.

Connecticut State Medical Society, New Haven, May 25-26. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

District of Columbia, Medical Society of the, Washington, April 25-27. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Executive Secretary.

Federation of American Societies for Experimental Biology, Toronto, Canada, Apr. 26-29. Dr. D. R. Hooker, 19 West Chase St., Baltimore, Secretary.

Florida Medical Association, Daytona Beach, May 1-3. Dr. Shaler Richardson, 111 W. Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Atlanta, Apr. 25-28. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.

Illinois State Medical Society, Rockford, May 2-4. Dr. H. M. Camp, 224 S. Main St., Monmouth, Secretary.

Iowa State Medical Society, Des Moines, Apr. 25-27. Dr. Robert L. Parker, 3510 Sixth Ave., Des Moines, Secretary.

Kansas Medical Society, Topeka, May 1-4. Mr. C. G. Munns, 112 W. 6th St., Topeka, Executive Secretary.

Louisiana State Medical Society, Alexandria, Apr. 24-26. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, Apr. 25-26. Dr. Walter Dent Wise, 1211 Cathedral St., Baltimore, Secretary.

Massachusetts Medical Society, Worcester, June 6-8. Dr. Alexander S. Begg, 8 Fenway, Boston, Secretary.

Minnesota State Medical Association, Minneapolis, May 31-June 2. Dr. B. B. Souster, 11 West Summit Ave., St. Paul, Secretary.

Mississippi State Medical Association, Gulfport, May 9-11. Dr. T. M. Dye, McWilliams Bldg., Clarksdale, Secretary.

National Gastroenterological Association, New York, June 1-2. Dr. G. Randolph Manning, 1819 Broadway, New York, Secretary.

Nebraska State Medical Association, Grand Island, May 2-4. Dr. R. B. Adams, 414 Federal Securities Bldg., Lincoln, Secretary.

New Hampshire Medical Society, Manchester, June 8-9. Dr. Carleton F. Metcalf, 5 South State St., Concord, Secretary.

New Jersey, Medical Society of, Atlantic City, June 6-8. Dr. Alfred Stahl, 55 Lincoln Park, Newark, Secretary.

New Mexico Medical Society, Gallup, May 11-13. Dr. L. B. Cochenour, 219 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Syracuse, April 24-27. Dr. Peter Irving, 2 East 103d St., New York, Secretary.

New York State Association of Public Health Laboratories, Valhalla, May 8. Miss Mary B. Kirkbride, New Scotland Ave., Albany, Secretary.

North Carolina, Medical Society of the State of, Cruise to Bermuda, May 9-14. Dr. T. W. M. Long, Roanoke Rapids, Secretary.

North Dakota State Medical Association, Fargo, May 8-10. Dr. Albert W. Skelsey, 20½ North Broadway, Fargo, Secretary.

Ohio State Medical Association, Toledo, May 3-4. Mr. C. S. Nelson, 79 E. State St., Columbus, Executive Secretary.

Oklahoma State Medical Association, Oklahoma City, May 1-3. Dr. L. S. Willour, Third and Seminole, McAlester, Secretary.

Rhode Island Medical Society, Providence, June 7-8. Dr. Guy W. Wells, 124 Waterman St., Providence, Secretary.

Society for the Study of Asthma and Allied Conditions, Atlantic City, N. J., Apr. 29. Dr. W. C. Spain, 116 E. 53d St., New York, Secretary.

Society of Surgeons of New Jersey, Elizabeth, May 31. Dr. Walter E. Mount, 21 Plymouth St., Montclair, Secretary.

South Dakota State Medical Association, Aberdeen, Apr. 24-26. Dr. Clarence E. Sherwood, Madison, Secretary.

Texas, State Medical Association of, San Antonio, May 8-11. Dr. Holman Taylor, 1404 West El Paso St., Fort Worth, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

17: 1-130 (Jan.) 1939

Cyanosis in Mitral Stenosis. P. Cossio and I. Berconsky, Buenos Aires, Argentina.—p. 1.

*Coronary Artery Disease Analyzed Post Mortem, with Special Reference to Influence of Economic Status and Sex. W. H. Gordon, E. F. Bland and P. D. White, Boston.—p. 10.

*Isolation of Nicotine from Human Urine. O. M. Helmer, K. G. Kohlstaedt and I. H. Page, Indianapolis.—p. 15.

Tissue Pressure: Objective Method of Following Skin Changes in Scleroderma. W. A. Sodeman and G. E. Burch, New Orleans.—p. 21.

Postphlebitic Varicose Ulcer: Surgical Treatment, with Special Reference to the Communicating Veins of the Lower Leg. R. R. Linton and J. K. Keeley, Boston.—p. 27.

Intracranial Vascular Lesions. W. M. Craig, Rochester, Minn.—p. 40.

Effect of Mediastinal Lesions on Pressures in Antecubital and Femoral Veins: Report of Fifty-Two Cases. H. H. Hussey, Washington, D. C.—p. 57.

Bilateral Carotid Sinus Denervation in a Patient Having Syncopal Attacks and a Congenital Vascular Anomaly: Report of Unusual Case. A. H. Elliot, N. T. Ussher and C. S. Stone, Santa Barbara, Calif.—p. 69.

Thrombophlebitis Migrans: Case Report. L. Hirschhorn, J. R. Lisa and R. J. Goldstein, New York.—p. 76.

Ventricular Extrasystoles Induced by Electrical Stimulation of the Exposed Human Heart Rotated 30 Degrees Counterclockwise on Its Vertical Axis. C. J. Lundy, I. Treiger and R. Davison, Chicago.—p. 85.

Study of Transverse Diameter of the Heart Silhouette with Prediction Table Based on the Teleoroentgenogram. H. E. Ungerleider and C. P. Clark, New York.—p. 92.

Coronary Artery Disease.—Gordon and his co-workers tried to determine the influence of the "economic status" on the general incidence and distribution of coronary artery disease. They examined the postmortem records of 600 economically well-to-do patients and for comparison 2,800 patients from the public wards of hospitals. The incidence and degree of significant coronary artery disease occurring in these two groups were determined. The public ward patients came largely from the low middle class of wage earners, many of whom were able to pay in part for their hospitalization. The data show that after the age of 70 years there is no difference in the incidence of coronary artery disease in men and women. Before that age there was much more in men than in women. The disproportion was most pronounced in young adults, the approximate ratio was three young men to one woman. This unequal incidence was evident in both coronary disease and complete occlusion. The relative incidence and the degree of coronary atherosclerosis were found to be significantly greater in the 600 private patients than in the 2,800 general ward patients. The greatest difference occurred in the middle-aged patients, in whom coronary occlusion was found to be twice as frequent in the private group. This difference was most striking in middle-aged men. These observations are in general agreement with clinical impressions.

Nicotine in Human Urine.—Helmer and his colleagues isolated nicotine, as crystalline oxalate and picrate, from the urine of persons who smoke. Its pharmacologic properties are the same as those of pure nicotine. They found that most of the nicotine disappears from the urine within three to four days after smoking is discontinued. Nicotine appears to be the substance responsible for the marked pressor action of many specimens of urine. Unless tobacco has been eliminated as a source of pressor substance in urine, conclusions relating urinary pressor substances to arterial disease are not justifiable. It has been suggested that nicotine might be retained by the body when there is a decrease in renal function.

Annals of Internal Medicine, Lancaster, Pa.

12: 907-1174 (Jan.) 1939

Experimental Heart Disease. G. E. Hall, Toronto.—p. 907.

*Pneumococcic Lobar Pneumonia: Report of 245 Cases, with Special Reference to Specific Serum Therapy. B. Horn, Bridgeport, Conn.—p. 922.

Urinary Diastase in Acute Pancreatic Necrosis: Experimental Investigation. C. J. Smyth, Ann Arbor, Mich.—p. 932.

Effect and Rate of Removal of Pyruvic Acid Administered to Normal Persons and to Patients With and Without "Vitamin B Deficiency." R. W. Wilkins, Soma Weiss and F. H. L. Taylor, Boston.—p. 938.

Acute Disseminated Lupus Erythematosus, a Systemic Disease. E. Rose and D. M. Pillsbury, Philadelphia.—p. 951.

The Aging Process: A Medical-Social Problem. G. M. Piersol and E. L. Bortz, Philadelphia.—p. 964.

*Clinical Study of Malignant Hypertension. I. H. Page, New York.—p. 978.

The Problem of Rheumatism and Arthritis: Review of American and English Literature for 1937 (Fifth Rheumatism Review). P. S. Hench, Rochester, Minn.; W. Bauer, Boston; M. H. Dawson, New York; F. Hall, Boston; W. P. Holbrook, Tucson, Ariz., and J. A. Key, St. Louis.—p. 1005.

Pneumococcic Lobar Pneumonia.—In two and a half years Horn states that 245 cases of lobar pneumonia were encountered. Of these 164 were of type I, II, V, VII, VIII or XIV pneumococcus pneumonia, for each of which specific serum is available. There were 104 type I cases, eighty-four of which were treated with serum, with a mortality of 3.6 per cent. This was in contrast to a 10 per cent fatality in the type I cases not treated with serum. Of thirty-three cases of types V, VII, VIII and XIV pneumonia treated with specific serum the mortality was 3 per cent compared to 12.5 per cent in the non-serum treated cases. Only three cases of type II pneumococcus pneumonia were observed. Serum was given and prompt crisis occurred, with recovery. In the total of 120 serum treated cases the death rate was 3.3 per cent while in the 125 non-serum treated cases the mortality was 16.8 per cent. Serum sickness was observed in only twelve cases. Cutaneous and eye tests for sensitivity can reduce serious serum complications to a negligible minimum. From his experience the author believes that type I serum should be given as early as possible and in large amounts, no matter how late the patient is seen. Also all patients having pneumonia of the types for which therapeutic serum is available should be given the benefits of specific serum therapy.

Malignant Hypertension.—Page states that the diagnosis of malignant hypertension was made in thirty cases when the following morbid changes were observed: (1) hemorrhage and papilledema in the eyegrounds, (2) normal or moderately reduced renal efficiency (unless the disease was of relatively long duration), (3) rapid advance of the morbid changes, (4) elevated arterial pressure often with immoderately high diastolic pressure and (5) normal or slightly reduced plasma proteins and hemoglobin. Malignant hypertension appears to be a syndrome of varied origin. Both men and women suffer from it, men more often. It is a disease of early middle age but may occur in youth or late middle age, seldom in old age. As a rule, hypertensive-vascular disease in the family is not common. It is not unusual for these patients to have had scarlet fever. The chief complaints are headaches, visual disturbances and fatigue. Far less frequent are dyspnea, convulsions, fainting, weakness, precordial discomfort and edema of the ankles. As a rule striking contrast exists between the neurotic behavior of patients with essential hypertension and equable emotions of those with malignant hypertension. The kidneys produce few symptoms. Nausea and vomiting occur often. Severe loss of weight is common. The simultaneous occurrence of these symptoms and signs bode ill for the patient's life. Impressive both to patient and physician is the sudden occurrence of blindness in one eye due to hemorrhage. The results of physical examination usually convince one that the syndrome is rapidly progressive and bears little resemblance to the chronicity of essential hypertension. The heart may not have time to hypertrophy, but dilatation of marked degree is not unusual. Laboratory examination discloses that the heart is seriously injured. This is shown especially by inversion of the T waves in leads 1 and 2. The function of the kidneys may be only moderately impaired until within weeks or months of death, at least as measured by urea clearance or the maximal ability to concentrate urine. More than the normal number of erythrocytes

is found in the urine, indicating that the renal blood vessels have not escaped morbid changes. Hemoglobin in the blood is normal or moderately diminished in the early stages. During the terminal phase it may be sharply reduced. These changes resemble those of chronic nephritis rather than those of essential hypertension.

Annals of Surgery, Philadelphia

Pilonidal Sinus.—Gage divides pilonidal sinuses and cysts into four groups: (1) sacrococcygeal dimple and sacrococcygeal dimple sinus, (2) true pilonidal sinus confined to the subcutaneous tissue, (3) true pilonidal sinus extending into the sacral canal and (4) true pilonidal sinuses which are continuous with the subarachnoid space and canal of the spinal cord. He describes a method by which surgical excision and primary suture will give a high percentage of cures and a low incidence of recurrence. After the sinus tract has been defined and stained the operative procedure is as follows: With the patient in the prone position a pillow is placed beneath the pubes, and straps of adhesive tape are applied to the buttocks on either side and fastened to the table. The straps separate the buttocks and act as retractors. In the noninfected type an incision can be made directly into the sinus, the sinus easily dissected from the surrounding tissue with a minimal loss of tissue and the resulting wound closed by suture. However, in the majority of instances secondary sinuses are present and necessitate a more extensive dissection. An elliptic incision is made around the primary opening of the sinus and extends down to the periosteum over the sacrum or sacrococcygeal region. If necessary a probe is introduced from the mouth of the accessory sinus through the tract into the open wound, facilitating the dissection of the secondary sinus tracts. The wound is thoroughly inspected and remnants of the sinus tract are searched for and dissected. All bleeding points are ligated with fine silk and the wound is closed by retention sutures of silk or silkworm gut. After closure of the wound edges a dead space is present at the bottom of the wound. If this dead space is not obliterated a recurrence will take place. Complete apposition of all wound surfaces and obliteration of all dead spaces is secured by pressure over the wound. This pressure must be constant and distributed evenly and is obtained by the use of moistened sea sponges. This pressure dressing is left undisturbed for a period of from ten to twelve days. If it becomes necessary to change the dressing, the sponge pressure must be repeated. The author used the foregoing method in forty-two cases of pilonidal sinus, without a single recurrence. There have been nine cases of cutaneous infection with good healing and in one a deep infection which necessitated wound opening developed, but this healed by open granulation. Strug has used the same method in fifty-four cases, with primary healing of the wound in fifty-two. Streptococcic gangrene of the skin developed in one case and serum accumulated in the wound in the other; this was aspirated three times before healing was completed. There have been no recurrences in his cases.

Gas Gangrene Following Therapeutic Injections.—A total of eighty-six cases of gas gangrene following the injection of medicaments have been reported, one of which is cited by Harney. Seventy-six of the eighty-six cases terminated in death. This figure is in marked contrast to the mortality of 49.7 per cent in 607 collected cases of gas gangrene following various injuries. The sites of injection were stated in fifty-nine of the reported cases and of these fifty-five were in one or both thighs, the buttocks or the abdominal wall. In nearly all cases reported, cultures were taken of the drugs, syringes, needles and solutions. A preparation of caffeine and digitoxin was found by Heuss to contain gas organisms. Nauwerck found gas bacilli in a preparation of caffeine sodium salicylate solution. Semenoff and Anschutz were able to find gas bacilli in cultures from the needles used in their cases. Dimtza found gas bacilli in one syringe, one needle and four files of the type used in breaking glass ampules. In all other instances in which studies were carried out the drugs, solutions, syringes and needles were found to be sterile. The most frequent diseases from which the patients given the injections suffered were pneumonia, typhoid and malaria. In twenty-one cases clinical symptoms of gas gangrene appeared between ten and thirty-six hours following the contaminated injections. The time elapsing between the appearance of the clinical symptoms and death varied from one to seven days in forty-five cases. It is considered highly significant that fifty-five of fifty-nine contaminated injections were given into areas of the body surface which might easily be soiled by fecal material. For this reason these areas should be avoided when giving hypodermic or intramuscular injections. However, if they must be used the skin should be sterilized instead of receiving the perfunctory dab with a sponge which is customary in most hospitals.

The Thyroid Gland in Mongolism.—Benda points out that facts seem to indicate that hyperthyroidism during the prenatal period is a cornerstone on which rests the explanation of mongolism. Pathologic study of the thyroid in fourteen cases of mongolism reveals that alterations are invariable. These consist in involutional changes: distention of acini, filled with colloid and composed of low epithelium; folding and confluence of acini; diffusion of colloid in the surrounding spaces; overgrowth of epithelium in thick piles, like an adenomatous growth, without formation of new vesicles; changes in the form and shape of the epithelium; increase in stroma, and degeneration of glandular tissue. The changes seen in mongolism differ from those in myxedema and suggest a temporary stage of hyperfunction or dysfunction. It is not known whether the thyroid in mongoloid infants worked too effectively or too early. It is more probable that the condition results from other

influences which affected the embryo. There may be the influence of the maternal thyroid or some other stimulating factor resulting from unbalance of the maternal endocrine glands. There may be also stimulation through some other endocrine gland in the mongoloid organism itself. The microscopic appearance of the thyroid in mongolism reminds the author of the histologic changes seen in cases of pituitary disease.

Mixed Tumor of Lacrimal Gland.—Sanders discusses the records of twelve proved cases of mixed tumor of the lacrimal gland. Ten of the patients have been followed for more than two years. The presenting symptoms in the twelve cases were essentially those of a slowly growing orbital tumor. The most striking symptom was exophthalmos, for which the patient sought medical advice. In several instances this was first noted by persons other than the patient. Probably the most consistent diagnostic finding was the presence of a palpable mass in the region of the lacrimal gland under the outer half of the superior orbital brim. The earliest ocular complaint was transient, indefinite diplopia. As the mass increased in size this was accompanied by a limitation of movement. In six cases there was marked loss of vision below 3/60 when the patients were first seen, and two patients had moderate loss of vision. The vision of six was normal, but in these cases there was usually subsequent loss as the condition progressed. In the majority of cases the onset was insidious, with a slow but steady progression of symptoms. The patients complained of surprisingly little pain or discomfort. Several had an occasional dull ache in the orbit. The general health of practically all the patients was good. Of eleven cases in which surgical treatment was employed, there was recurrence in ten. One patient refused operation and died in six years with marked local invasion and metastases to the liver, lung and mediastinum. Four of the patients had metastases. Five are dead from intracranial extension due to a marked tendency for bony invasion. Microscopically the growths seem identical with mixed tumors of other locations. The invasive element seems to be the epithelium. The recurrence is probably due to incomplete removal. Pathologically the mixed tumors are probably a definite pathologic entity of dual origin, with the characteristic tendency of the epithelial element to become locally invasive. Irradiation is of little aid and early complete surgical removal is indicated. If there is evidence of bony invasion, a resection of the entire tumor-bearing area is indicated; but, if the invasive tumor is limited to the soft tissues, exenteration may be sufficient.

Prognosis of Insured Neurotic Persons.—Denker followed up 1,000 disability claims in which the diagnosis was psychoneurosis. These claimants were all insured and if totally disabled received varying amounts of money in monthly payments depending on the amount of insurance carried. The disability occurred from one to twenty years after the insurance policy was issued. The diagnosis in all instances was made by a physician and often corroborated by a nerve specialist. In the New York area most of the cases were examined by the author himself. Total disability was recognized only after the insured had been ill for at least three months and to an extent that would prevent him from engaging in any occupation for remuneration or profit. The milder or more transient neurotic disturbances are therefore automatically excluded from this study. The follow-up study was made at least five years and, in many cases, from ten to fifteen years after disability had commenced. The great risk of error in labeling a patient neurotic became apparent early in the study. It was found that 293 cases had been erroneously diagnosed "psychoneurosis," the true nature of the illness manifesting itself in most cases within one year as some organic disorder. The age at onset of the neurosis in the 707 true neurotic persons varied from 19 to 59 years, the average age being 37.2 years. This is in contrast to the slightly higher average age of the erroneously diagnosed group, in which 40.8 years was obtained. It appears that middle age in the male produces the greatest neuroses, possibly because his responsibilities are greatest and his career made or broken at this period. In the female this age incidence is somewhat lower. Of the 707 patients, 384 were men and 323 women. However, only from 12 to 14 per cent of the insurance policies during these years (1915 to 1930) were held by women. Neuroses were therefore from three to four times as frequent among insured women as among insured men, which corresponds with the clinical frequency of neurosis in women. No definite conclusions can be drawn as regards occupation, but there is a definitely high incidence of neurosis among clerical workers, executives, teachers and professional people in contrast to the greatly diminished number among manual workers and housewives. Only forty-five of the 707 truly neurotic patients gave a history of a familial mental taint. There were eighteen male

and four female deaths in the entire series, death being due to various causes. Approximately three fourths of the patients recovered within two years of the onset of their neurosis. A little less than half recovered within the first year. It seems that neurotic persons receiving $200 or more per month, who have been ill for three years, practically never get well. The monthly disability check appears to eliminate the incentive to get out and fight life's struggles and, in addition, it acts as a constant reminder to the highly suggestible, mentally ill patient that he is disabled. It appears that it would be much wiser to pay these claims by some form of lump sum settlement at the end of the first year of disability or sooner.

Aseptic Necrosis of Bone.—Kahlstrom and his co-workers report the results of a clinical and roentgenologic study of four cases of caisson disease with extensive changes in the skeleton. One case came to necropsy and in another a biopsy was performed on the involved head of the femur. Extensive lesions were revealed in diaphyses and in epiphyses of certain bones with changes in the joints. The evidence appears to be conclusive that the primary lesion is an accumulation of nitrogen gas in the bones—intravascular or extravascular—with circulatory interference and a resultant massive aseptic necrosis. In the head of the femur or humerus the necrotic lesions may break down and be invaded and eventually replaced by new bone or fibrous tissue. Invasion of portions of the epiphysis may be followed by calcification and arrested transformation, especially in portions of the epiphysis away from the articular surface. Involvement of the articular cortex and cartilage leads to the slow development of arthritis deformans with or without osteocartilaginous loose bodies. The lesions in the shafts are much more numerous and extensive than in any reported case of bland infarction or aseptic necrosis of bone. The necrosis was of the interior of the diaphysis in all instances. It is difficult to state whether the lesions in the bones produced by the nitrogen gas were the result of nitrogen embolism or of nitrogen accumulation within the medullary cavity and direct compression of blood vessels and other tissues or a combination of the two. Lesions of the soft parts are known to be produced by both methods. Points in favor of nitrogen embolism are that (1) the lesions were frequent (in three cases) in the heads of femurs in which the end arteries are known to be found frequently and (2) the metaphyses of the lower end of the femur and of the upper end of the fibula and both ends of the tibia were affected in some cases while their epiphyses escaped, which would favor embolism of the branches of their nutrient arteries. Points against the embolic theory are (1) the enormous size and symmetrical distribution of the necrotic areas and (2) absence of involvement of the bones of the trunk. In favor of the local pressure on blood vessels and other tissues of nitrogen gas accumulated in the medullary cavities is the limitation of the process to the bones of the extremities. These bones are rich in fatty marrow, while the bones of the trunk which have higher temperatures than the bones of the extremities (Huggins and Blocksom) contain hematopoietic marrow. Since fats and lipoids are known to absorb approximately five times as much nitrogen as other tissues, more nitrogen should be liberated within the bones of the extremities than within the bones of the trunk in caisson disease. The best treatment of any form of necrosing lesion of the head of the femur (including caisson disease necrosis) is prolonged abstinence from weight bearing, thus permitting reorganization of the necrotic area, and if possible replacement by new bone with the avoidance of collapse of the head.

Intradermal Test for Pregnancy.—Parsons found that the intradermal test, according to the results obtained in 100 pregnant women and forty postpartum or known nonpregnant women, gives an unreliable test for pregnancy, since it was inaccurate in both the control group and in the known pregnant group with an error of from 4 to 72 per cent. In the early months of pregnancy, error of as high as 72 per cent was obtained. Age, menstruation, days post partum and duration of pregnancy had little influence on the readings. Follutein was found to react more often both in the pregnant and nonpregnant groups, owing perhaps to a protein reaction rather than to the gonadotropic hormone present. Difficulty was experienced in making the readings, as pigmentation of the skin and degrees of erythema were influencing factors which often left in doubt the classification into which the test should fall. From a review of the 679 cases in which the intradermal skin test was performed, the test has proved entirely unreliable in the hands of the workers who have attempted to repeat the work of Gilfillen and Gregg. There seems to be no choice among the various hormone preparations used; all yield equally unreliable results.

Tuberculosis in Anal Fistula.—In order to clarify, if possible, the controversy regarding tuberculosis as a cause of anal fistula, Buie and his colleagues studied 206 consecutive cases of anorectal fistula. Guinea pigs that received subcutaneous injections and those that received intraperitoneal injections of tissue from eleven patients died within three weeks. This low percentage of failures can probably be accounted for by the fact that a method of attenuation of the colon bacillus was employed. More deaths occurred before this time limit expired in the cases of those guinea pigs injected intraperitoneally than occurred after the time limit. Of the 195 cases (94.7 per cent) studied successfully and completely, tuberculosis was not found in 163 cases. In thirty-two cases, evidence of the presence of tuberculosis was found somewhere in the body. Of this group of thirty-two cases, ten gave evidence of a tuberculous "focus"; that is, seven showed healed or inactive pulmonary tuberculosis, two an active pulmonary lesion and one tuberculosis of the cervical lymph nodes. Inoculation of animals, routine histopathologic studies and subsequent study of numerous sections of tissue did not reveal evidence of tuberculosis in the anorectal fistula. Inoculation of animals gave positive results in twenty-two cases, whereas routine microscopic study of sections from an adjacent piece of fistulous tissue gave positive results in only eight cases. These results approach closely those of other

investigators who have used the same method of studying sections of a similar nature. Of the twenty-two patients who were proved to have a tuberculous fistula, seventeen were shown to have, in addition, a so-called focus of tuberculosis elsewhere in the body. In one of the remaining five cases the organism was demonstrated in sections of tissue taken from the fistula. In the twenty-two cases in which positive results were obtained, the average time required for healing was seventy-three days as compared with an average of twenty-nine days in the 173 cases of nontuberculous fistula. Whether a fistula is tuberculous or not should not alter the type of treatment employed.

Fat Necrosis of Breast.—Livingston and Lederer present two cases of fat necrosis of the breast. The first case is particularly instructive because, although it fulfilled all clinical criteria for a diagnosis of a malignant growth, it proved to be a benign lesion. The diagnosis made preoperatively was carcinoma and a radical amputation was performed. In the second case a correct preoperative diagnosis was made and only the lesion was removed. If one was to speculate regarding the cycle of evolution of fat necrosis, it can be said that first either there is trauma from external causes or direct pressure of the breasts from their own weight. If the trauma is severe with injury to blood vessels, one may see areas of ecchymosis. If the trauma extends more deeply there may be no visible evidence of blood extravasation. The presence of pigment in cells suggests that there has been hemorrhage. There is a fat splitting ferment (lipase) in the blood as well as in the fat itself. Fat tissue, being unstable, breaks down easily into its constituents, fatty acids and glycerin. Fat necrosis and fat splitting are two different processes frequently allied, necrosis being the principal event and fat splitting only an accompaniment. The necrosis of fat tissue accompanied by a splitting into fatty acids and glycerin is considered to be a degenerative phase which is closely followed by repair. This repair is characterized by the appearance of spindle, round and giant cells (Menville). Since the majority of fat necrosis is subcutaneous, the fibrous repair tissue acts like strong cords which have no elasticity but have a tendency to retract. Adair states that, early in the cycle of fat necrosis, small cysts may form. After several years these cystic cavities may contain a mixture of small and large calcareous masses. If these tumors are left undisturbed, the contents and wall of the cyst solidify into a calcareous mass. Fat necrosis more closely resembles carcinoma than other benign lesions. The treatment is local excision of the tumorous mass.

Immune Transfusions in Venereal Lymphogranuloma.—Brady points out that of sixteen patients with venereal lymphogranuloma given transfusions from immune donors (having had the disease and recovered from it not less than ten weeks before) all showed distinct clinical improvement in mental attitude, color, appetite and definite increase in weight. The disease may be one in which immunity is acquired with formation of immune bodies in the blood stream. The author believes that immune transfusion as a therapeutic agent is worthy of further investigation in this condition and to verify his results. The possibilities of the blood bank are widened if the foregoing results are verified. The naval service offers an excellent opportunity for this study both because of the prevalence of the disease and because of the number of donors obtainable.

Inguinal Lymph Gland Biopsy in Tuberculosis of Knee.—Two and a half years ago it was suggested to Seddon (by Fitzgerald) that examination of an inguinal lymph gland on the affected side of a joint suspected of tuberculous infection might give valuable information. For removal of the gland local anesthesia is employed, except in small children. The operation is a biopsy and nothing more. The results in the diagnosis of eighteen cases of tuberculous disease of the knee are given. In a few of these cases inguinal biopsy was not required to establish the diagnosis; since material from the knee was available, however, the author felt justified in removing glands from these patients in order to establish the reliability of the method. There were only three negative results in the series. A positive result is of the greatest possible value, but a negative one cannot be taken to exclude tuberculous disease of the joint. To ensure himself that a positive result could not possibly be fortuitous the author removed glands from other regions in four cases, in none of which was there any evidence of tuberculous disease. Since gland biopsy is a worthwhile procedure, the next step is to apply it in doubtful cases of arthritis of other joints. The merit of the method is its simplicity and safety.

Benign Lymphocytic Meningitis. D. A. Cannon.—p. 1.
*Survey of Results of Fractures of Long Bones of the Lower Limb. A. M. Murray.—p. 9.

Fractures of the Lower Limb.—Murray gives the results with fractures of the femur obtained from 1926 to 1935 and of the tibia and fibula from 1932 to 1936 inclusive. Only those cases about which detailed information was available are included in the tabulation of the results. Many of the older patients have died subsequently as the result of other illnesses. Considerable numbers, chiefly of male patients, have been lost sight of owing to the recent migration to England of workers in heavy industries, which in itself presupposes a satisfactory result. The total number of fractures of the femur in males more than 15 years of age was seventy-six. Of these twenty-nine were fractures of the neck of the femur and forty-seven were fractures of the shaft. Nine patients died in the hospital. There were seventy-seven fractures of the femur in females more than 15 years of age. Fifty-four were fractures of the neck and twenty-three were fractures of the shaft of the femur. Eight deaths occurred in the hospital. The total number of fractures of the femur in children up to 15 years of age was seventy-seven, all of which were fractures of the shaft. There were three deaths. There were 214 fractures of the bones of the lower leg: ninety-six in males and fifty-three in females more than 15 years of age and sixty-five in children less than 15 years of age. Only seven deaths occurred in the hospital in this group of patients. Apart from those with immediately fatal results, no patients were subsequently unfit for any occupation. Primary amputation was necessitated owing to damage to the soft tissues and vessels in only two cases. Quite a number of the patients had had both legs broken at the same or different times. When one leg had been operated on and the other treated conservatively the patient maintained that the leg on which the operation was performed was less easily fatigued than the other one. In no case in which operative measures were adopted did nonunion of the bone follow. Since the introduction of stainless steel there has been less reaction in the tissues than formerly. Sepsis following operative treatment of a compound fracture occurred in a few instances but always cleared up quickly leaving no permanent ill

effects. Good results (provided that reduction is efficient) seem to depend to a large extent on (1) the amount of damage to the soft tissue rather than purely bony damage and (2) the patient himself, particularly when he has reached the ambulant stage and is no longer in need of hospitalization. After-treatment appears to be as much a social as a medical problem. The financial aspect is of primary consideration in many cases. Perhaps some arrangement could be made whereby the ambulant patients would be sent out to camps and encouraged to do all sorts of odd jobs and to play games in a modified way until they were fit to return to work. Should they be unfit for their original employment, the onus of finding other work should fall on the former employer. In this way, although the patient would not benefit financially, his incentive to complete recovery would be greater and there would be less scope for the malingerer.

Infections with Rickettsia of Q Fever.—Burnet and Freeman describe a series of mild or subclinical laboratory infections with Q fever. The infections were recognized by serologic tests—rickettsial agglutination and protection tests in mice. A mite, Lyponyssus bacoti Hirst, is suspected of being the responsible vector from experimentally infected mice. The mode of infection has not been definitely determined. Since two of the five laboratory workers infected have never worked with the organism, and one of them has been entirely engaged in clerical work, it is strongly suspected that the infection was carried by some freely moving arthropod vector. Mice have been used as laboratory animals in practically all the work on Q fever, and the human infections must have arisen eventually from these. Two ectoparasites are present in the authors' stock of mice; the common mouse louse, Polyplax serrata, is almost always to be found in small numbers and the blood-sucking mite Lyponyssus bacoti Hirst has appeared at times in large numbers. At other times the stock appears to be free from this parasite. Circumstantial evidence points strongly toward the mite, which moves freely and is known to bite human beings, as the responsible vector; but no experimental evidence of its capacity to transmit infection has been obtained.

Q Fever in Laboratory Workers.—Smith and his associates cite two cases of laboratory infection with Q fever. In each case the Q virus was found in the patient's blood by guinea pig inoculation, and Q agglutinins were demonstrated in the serum during convalescence. The infections were associated with mouse experimentation. While the mite Liponyssus bursa (Berlese) was present at times on the mice and was therefore a potential vector, the authors ascribe the infections to direct contact with infective mouse tissues.

*Complex Mechanism of Edema in Patients with Heart Disease. J. Doumer.—p. 183.

Mechanism of Edema in Heart Disease.—Doumer says that the edemas of patients with cardiac disorders are generally attributed to purely mechanical factors. Cardiac insufficiency causes disturbances in the peripheral circulation, which in turn leads to stasis and to venous hypertension. The latter causes excess pressure in the capillary network and, under the influence of this excessive hydrostatic pressure, serous transudation and edema develop. This explains certain edemas of cardiac origin but it does not seem to explain all of them. The edemas seem to be of a more complex nature in patients with aortic defects, with hypertension, with coronary lesions and in those with cardiac insufficiency with normal heart and presenting the aspects of left-sided ventricular insufficiency. It is known that left-sided ventricular insufficiency does not produce peripheral edemas or at least it does not produce them until the secondary insufficiency of the right side of the heart has developed. The edemas which complicate the syndrome of insufficiency of the left ventricle are not hard and they pit readily. Moreover, they are not cyanotic but pale like those of patients with renal disease. The author further discusses the hydropigenous factors of a humoral or tissular type, then the noncardiac edemas of patients with heart disease and finally the cardiac insufficiency that is of edematous origin. He reaches the conclusion that the edemas of patients with heart disease are mechanical edemas only in certain cases and to a certain extent. In the development of edematous infiltration there enter multiple factors, some of which are probably only indirect consequences of the progressive cardiopathy. As long as these factors are incompletely understood it is impossible to draw practical conclusions. Once they have been penetrated, however, it will doubtless be possible to face the problem of the treatment of the edemas as well as of certain conditions of heart failure if it is confirmed that certain hydropigenous conditions may exercise secondarily a harmful action on the function of the myocardium.

*Clinical Value of Coaguloretractovisometry in Internal Diseases. L. Blacher.—p. 140.

Coaguloretractovisometry in Internal Diseases.—Blacher says that he has employed his own method of coaguloretractovisometry on the blood of 147 patients. Describing this method in a previous report, he differentiates between "the reaction of coagulability" (coagulation of the upper layer of the blood) and "the reaction of coagulation" (coagulation of the lower portion of the blood). Moreover, he distinguishes between the "time of the reaction of coagulability" (the time elapsed from the mixture with the reagent to the moment of appearance of coagulation) and the "time of the reaction of coagulation" (interval required for the coagulation of the remaining blood). In the present report he finds that the variations of the coagulability of the blood, which are ascertained in diverse internal diseases, are typical for each particular disorder. Not only are the quantity, quality and amplitude of the deviations of the evolution of the coagulability characteristic for the more or less grave forms of the hemorrhagic conditions, but they reveal the nature of the pathogenic agent and the length of time it has been active. In morbid states there are observable modifications not only of the reactions of coagulability but also of the structure of the clots. According to their physical properties, the clots can be classed as hard, soft, liquid and "sanguinolent." The marbling of the clotted blood, which the author observed most frequently in cases of hemorrhagic disturbances of the hepatosplenic system, indicates the absence of the reaction of retractility in the clotted blood. The variations in the course of the coagulability of the blood in the hypochromic anemias indicate either impending hemorrhage or occult bleeding. In pernicious anemia, liver treatment exerts

a perceptible action on the retractility of the coagulated blood, particularly the retractive force of the clot. The oscillations of the phase of coagulability do not depend on the evolution of the reaction of retractility and on its force; on the contrary, the retractive force of the coagulum depends most often on the evolution of the reaction of retractility of the clotted blood. The peculiarity of the detected traits in the coagulability in the course of diverse diseases procures for each of these diseases a new pathognomonic symptom, which may be helpful both in the diagnosis and in the prognosis. The variations in the coagulability of the blood are directly related to the condition of the liver and of the spleen. The spleen exerts an inhibiting effect on the course of the coagulation and especially on the reaction of the retractility of the clot. The liver is the principal producer of the substances that are necessary for the process of coagulability, whereas the spleen regulates the process. The variations of the course of the reactions of the coagulability of the blood are concomitant to the corresponding oscillations in all the corpuscular system of the peripheral blood. The strongest modifications of this phenomenon have been revealed in the course of a thrombopenia with a thrombocytic formula "deviation to the right" without acrochromatic or achromatic platelets.

*Perforated Cholecystitis: Anatomoclinical Variations. J. A. Caeiro.—p. 638.

Perforated Cholecystitis.—Caeiro reports six cases of perforation of the gallbladder in the course of calculous cholecystitis. He found that the condition is due to necrosis of the walls of the structure. The clinical and anatomopathologic forms of perforation depend on the type, either acute or benign, of the infection by which the evolution of perforation is controlled and also on the presence or absence of peritoneal adhesions. He observed that acute perforation takes place in gallbladders which contain fluid at great pressure or calculi obstructing the cystic duct. Perforation takes place at the point of greatest pressure or where the calculi are impacted. The gallbladder is not inflamed, although the walls are thickened. There are no adhesions from the structure. Perforation of slow evolution takes place in calculous cholecystitis of long duration. The gallbladders are filled with calculi and there are many adhesions through which the structure is joined with one or several visceral organs. Perforation takes place at the point of greatest pressure of the calculi or at the point of union of the gallbladder with adhesions. Perforation at the lower aspect of the gallbladder is frequently complicated by the formation of fistulas between the gallbladder and the colon and duodenum. That at the upper aspect of the structure is frequently complicated by fistula of the liver. In either case the gallbladder empties its contents into the organ with which it joins, through the fistula. Perforation of the liver is complicated by grave abscess of the liver and degeneration of the liver parenchyma. When perforation is at the lower aspect of the gallbladder there is a history of the patient with grave repeated infection, frequently with jaundice, inflammation or tumors at the subhepatic region, a grave peritoneal reaction and symptoms simulating gastric or duodenal ulcers. When it is at the upper aspect of the gallbladder, pain in the liver and acute hepatitis are the predominant symptoms. An early diagnosis is of importance. The treatment consists of cholecystectomy, at the end of which an ample drainage is left.

*Meningo-Encephalitic Complications of Typhoid in Children. E. Peluffo and C. E. Castells.—p. 35.

Meningo-Encephalitic Complications of Typhoid in Children.—According to Peluffo and Castells, typhoid bacteria have a special affinity for the nervous system, especially in children. The most frequent complications of typhoid in children are those involving the meninges or the brain with development of a special type of encephalitis. The acuteness of the complications vary in different cases. Meningitis is more frequent and less grave than the encephalitic complications. It may develop at any time in the course of typhoid. Sometimes the meningeal reactions are the predominant symptoms of typhoid, and again grave suppurative meningitis may develop. The encephalitic complications may cause bulbar, cerebellar ataxic, mesencephalitic, choreic, cortical aphasic, mental and epileptic symptoms. The prognosis of the complications, especially encephalitis, is grave. Until recently symptomatic treatment was resorted to, but satisfactory results have now been reported in the literature in cases of typhoid encephalitis from a treatment with immunotransfusion. The authors report four cases in children between the ages of 3 and 4 years. In none of the patients was immunotransfusion resorted to. Three patients died. The one who recovered has mental sequels.

Skin After Treatment with Cancerigenic Substances.—In this paper Dietrich reports studies on the part played by regeneration in the pathogenesis of experimental cancer. It was her aim to find answers to the following problems: 1. How does regeneration take place in skin that has been treated with cancerigenic substances? 2. Is it possible to produce cancer earlier in this manner than is possible merely by chemical irritation? 3. Is this production of malignancy due to a latent cancerigenic characteristic of the epithelium which becomes manifest as the result of the stimulus of regeneration, or is an action of the cancer producing substance on the general organism responsible for this special course of regeneration? The author made studies on sixty-six mice which had been treated with cancerigenic substances (tar and benzpyrene). After various periods of time, pieces of skin were removed from the site that had been painted with cancerigenic substances and from another site (posterior portion of the back). The pieces were sectioned and subjected to microscopic examination. The wounds were left open following the excision and after twelve days of regeneration another excision was made at the same sites and these pieces too were examined microscopically. It was found that, depending on the length of painting with the cancerigenic substance, the skin showed thickening of the epidermis with desquamation, formation of cones, papillomas or atypical proliferations. The pieces excised from the unpainted sites never showed changes in the epidermis; that is, they were identical with those from mice that had not been painted with cancerigenic substances. Thus the untreated pieces of skin gave no indication that the painting with cancerigenic substances had caused a general alteration in the organism. In two cases the regeneration on the untreated site showed more pronounced conical formations than is normally the case, but it would be going too far to conclude from this that painting of a site with cancerigenic substances causes general changes in the organism. The site that had been painted with cancerigenic substances showed considerable deviations of regeneration. During a certain stage of the painting with cancerigenic substances the added regeneration stimulates the as yet unchanged epithelium to an increase in layers, to greater cone formation and partly even to proliferation with atypical transformation. It may be said that by the addition of regeneration the epithelium is transformed from a precancerous into a cancerous condition. However, it appears that the proliferating epithelium or the one that has already undergone cancerous degeneration may show normal regeneration. The innate drive of the cell toward

regeneration with the aim of bridging a defect is not changed or inhibited by painting with cancerigenic substances. To be sure, the time required is usually somewhat longer than normal. In the final estimation of these studies in which the author also cites a report by Brunschwig, Tschetter and Bissel on "Wound Healing and Neoplasia," she says that her microscopic studies did throw some light on this relationship between regeneration and cancerigenic action. Her studies indicate that the tendency to proliferation is accelerated by regeneration and that the regeneration is the eliciting factor for proliferation, if an anlage to it existed previously.

Edema in Beriberi.—A deficiency in vitamin B_1 (aneurin) appears under two distinct clinical syndromes: (1) as a simple polyneuritis and (2) as a complex syndrome with polyneuritis, edema and a disturbance in the function of the heart and blood vessels. Studies by Meyers were made to determine the significance of the edema in beriberi. In most cases of simple polyneuritis the appearance of the nervous lesions is preceded by other, usually infectious, processes. This is not the case in beriberi. Moreover, the polyneuritides do not seem to be early forms of beriberi and the transformation of polyneuritis into beriberi seems to be the exception rather than the rule. On the basis of purely anamnestic information it was not possible to discover any difference in the dietetic insufficiency of the two types of patients. Heart disease is also absent in about half of the cases of polyneuritis without edema, and heart disease is present in 92 per cent of the cases of polyneuritis with edema. Yet it is hardly possible to consider the edema in beriberi as only of cardiac origin. The vascular syndrome after an injection of epinephrine which is typical for beriberi (Aalsmeer) is absent in the majority of cases of polyneuritis, and Volhard's diuresis test has a normal course in these cases. Volhard's test may have the same result in beriberi, in which the edema is of a pronounced transient character. These transient edemas represent probably the simplest and purest picture of the edema of beriberi. They are of a hydrostatic nature and seem to be caused by a lowering of the tonus of the arteriolar walls and by an increased tension in the capillary system. The epinephrine blood pressure curve (Aalsmeer) which is typical for beriberi seems to be a manifestation of this. The question why edema exists only in some of the cases of deficiency in vitamin B_1 thus leads to the inquiry after the causes of the circulatory failure. This question has not been answered as yet, but since treatment with aneurin cures the edema as well as the nervous lesions it seems probable that the first has an intrinsic rather than an extrinsic origin.

Acute Terminal Ileitis.—Harbitz reports two cases of acute terminal ileitis in youths aged 15 and 19 respectively. It was characterized by subacute onset, abdominal pain for from eight to ten days and then aggravation with severe pain in the right iliac fossa. On rectal exploration there was tenderness on the right side. There was a marked red thickening of the distal end of the ileum in one case; in the other, palpation of the intestine showed a leathery thickening like that in linitis plastica, but glandular enlargement dominated the picture, in the first case with one gland the size of a walnut and another the size of a pigeon's egg, in the second case with a hard glandular tumor about the size of a hen's egg. Acute terminal ileitis, the author says, may be considered as a distinct entity. Clinically it usually appears as an acute or subacute appendicitis. Although the affected portion of the ileum can hardly be palpated, the pronounced enlargement of the glands should be noticed. The disease occurs most often in the first two decades of life. Treatment should as a rule be exploratory laparotomy and appendectomy. The appendix is usually of fairly normal appearance and a relationship to the inflammation in the ileum is doubtful. The author expects certain roentgenographic changes in the lower part of the ileum seen in his cases some months after the laparotomy in the acute stage, probably as a result of the earlier acute ileitis, to disappear gradually, but continued observation is called for. He wishes to stimulate after-examination in cases of conservatively treated acute terminal ileitis. He adds that chronic terminal ileitis occurs most often in the third and fourth decades of life, usually with the symptoms of a chronic enteritis, and may resemble an ulcerous colitis; chronic diarrhea is most often the first symptom. Infiltrations develop in the lower ileum, with ulcerations, abscesses and perforations. The affected intestinal portion gradually becomes narrowed and a true ileus may occur. In addition to palpation, x-ray examination is of decisive significance. Treatment often consists of the employment of laparotomy with drainage, with later entero-anastomoses and finally resection.

Mitral Stenosis.—Jervell and Grytting studied 169 cases of mitral stenosis (in forty-four men, 125 women) observed during the last five years. In eighty-two (twenty-nine men, fifty-three women) there was history of one or more attacks of rheumatic fever. Fifty-nine (ten men, forty-nine women) had no history of diseases to be connected causatively with the valvular defect; these cases, predominating in women, are thought possibly to depend on a disposition in women to rheumatic infections without clinical symptoms. The rheumatic fever in most cases occurred between the ages of 10 and 20. Most of the patients were between 20 and 40 years of age, forty-four were over 50 and three over 70. The duration in the fourteen patients who died, aged from 24 to 65, was from two to twenty-eight years. Eighty patients had palpitations, which in nineteen were the first symptom. Fifty-eight reported pain in the heart region, fourteen of these typical angina pectoris; in five this symptom led to the diagnosis. When asystolia sets in, dyspnea dominates the picture; 134 had dyspnea during rest or on exertion, and in 121 it was the first symptom. The authors say that mitral stenosis in the first stage may be difficult to diagnose. A presystolic or diastolic murmur is the characteristic auscultatory observation. The diastolic murmur may be loud or soft, short or long continued. A systolic murmur was established in 118 of the 169 cases, clear diastolic murmur in 115, presystolic murmur in thirty and gallop rhythm in twenty-four. In six cases there was no certain murmur and in seven only a systolic murmur. X-ray examination is of great value in the diagnosis of mitral stenosis, electrocardiographic examination being less important. There is distention of the pulmonary artery, right ventricle and left auricle, and signs of pulmonary stasis are often present. "Mitral configuration" appeared in fifty-six cases (73.9 per cent), enlargement of the heart in fifty-four cases (71.1 per cent) and both "mitral configuration" and enlargement in 52.6 per cent. Compensatory hypertrophy of the heart can be anatomically established; dilatation is believed to occur first, and the enlargement of the heart established on x-ray examination is regarded as a dilatation. There was arrhythmia in 102 patients and hypertonia in nineteen, with permanent hypertension of more than 200 in only three. Mitral stenosis is not seldom combined with other valvular defects. If early diagnosis of mitral stenosis is made and the patient's manner of living regulated early, the asystolic stage may be avoided or at all events delayed.

SATURDAY, APRIL 22, 1939

The Legal Status of the Intern

FRED ELLSWORTH CLOW, M.D.

Secretary of the New Hampshire State Board of Registration in Medicine

WOLFEBORO, N. H.

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 14, 1939.

In the last quarter century twenty-one states and Alaska have made the hospital service a requirement for licensure. Some medical schools withhold the degree until one year at least has been served. In 1938 the Council on Medical Education and Hospitals reported for the United States 7,354 internships in 729 approved hospitals and for Canada forty-eight approved hospitals. In addition, clinical clerkships in teaching hospitals, where men have varying types of duties, furnish an opportunity for the student to become familiar with the service in advance of formal appointment. A change has been noted in the place of the intern in the educational scheme. Whereas in the past the service in the hospital was considered postgraduate training and optional with the student, longer training as a resident is now required and the intern is regarded more as an undergraduate, still pursuing his medical course, learning the art as well as the science of medicine. Longer periods of intern service are offered and consequently the assumption of more responsibility for adequate care of the hospital patient. With increased responsibility has come the necessity for wider knowledge, more maturity of judgment and better poise.

When the intern enters the hospital, he learns for the first time in his life that he is liable for his acts not only as an individual member of society but as a professional man. Besides, once the medical student comes in intimate contact with patients he is amenable to the statute governing the practice of medicine in his state. For the first time his every word and every act are scrutinized, often remembered and frequently misunderstood by a person rendered hypercritical by illness. The intern by a thoughtless remark alone can cause a malpractice suit for the physician referring the patient. Observations concerning previous diagnosis and treatment are particularly dangerous, because the patient rarely understands and never correctly describes any medical opinion or procedure.

COSTLY MISTAKES

With improvement in the technic of diagnosis and treatment and the consequent increase in mechanical manipulations, the opportunities for costly mistakes are enormously increased. A broken spinal puncture needle, the silkworm-gut suture left in the abdominal wall, the wrong solution injected into a body cavity, an infection following a trifling operation may cause the intern untold trouble with possibly the loss of reputation in the locality, the loss of money and indirectly great damage to the prestige of the hospital. Thoughtful men in all departments of medicine are disturbed at the way in which litigation is increasing, the ease with which it can be started, the complicated, costly, and to physicians the cumbersome methods of the Law. They are astounded at the ease with which the slightest slip in technic is magnified when presented to a jury of laymen, and the difficulty of getting the truth to prevail. The hospital may protect its property and its employees; the visiting staff can rely on the insurance company to assume liability. Apparently the intern, if attacked as an individual, is without protection. One insurance company in New England, with long experience in this field, offers no way in which the intern may be covered. Another company specializing in liability insurance replies: "Our Hospital Policy covers the liability of a hospital on account of the negligent acts of interns, resident physicians, and medical students. It will not, however, cover the liability of resident physicians, interns or medical students themselves." Insurance companies demand a certain competence, experience, medical society membership and the good opinion of men of the same standing. House officers cannot yet meet these standards. Besides, it appears that if a liability contract were devised the high cost would be a deterrent to many

young men still under expense of education. Until the legal status of the intern is determined by precedents or, better, by statute the hospital can scarcely afford to insure him.

The hospital has a selfish interest in protecting the intern from himself for its own salvation. One can but feel that too often the intern is given too much latitude in the conduct of ward service. No one believes today that an internship prepares any man to become a safe, conservative surgeon. And that often appears to be the aim of the student himself. Some of the dissatisfaction existing in unnecessary and harmful operative work done in private practice springs from the practice of permitting the house surgeon to do by himself operations for which he is not trained.

Many hospitals with a small resident staff require many routine administrative duties and the assumption of altogether too much responsibility in the performance of technical procedures. Hospital administrators complain that the intern is poorly prepared to do his job. But, as Dr. Lucius R. Wilson says, "The intern is suddenly transported from the environment of the medical school he knows so well and finds himself in a new hospital constructed and operated along different lines from the one he knew as a student. The hospital routines are different, its rules and regulations developed from years of experience with its particular problems are hard to understand. The staff have names with which he is unacquainted, he knows little, if anything, of their contribution to medicine; the hospital routines following different channels from those strongly entrenched in his mind."

As has been pointed out by more than one hospital executive, not only is the intern entitled to the conventional precedent book of routine matters but he should be introduced to his new duties by some one who will be a sympathetic adviser, who can interpret to the newcomer methods and customs of that hospital, in which otherwise he may grope and stumble during his whole appointment.

HOSPITALS ARE COMPLEX ORGANISMS

He should be taught that hospitals are complicated organisms, serving in a most personal manner the public made up of all types of individuals, dealing with persons sensitized by illness, with relatives and friends even more demanding and more critical. The opportunities for trouble in the hospital exist in every procedure, every minute of the day, and involve every employee and officer and every physical feature of the plant.

The intern is charged with the duty of carrying out the instructions of the attending physician except in emergency. When an emergency arises it is incumbent on the intern to exercise his own judgment until report can be made to the attending physician.

The intern may be charged with failure to obtain consent for an operation from a husband or the parent of a minor. Care must be used that state laws are observed. Permission should be reviewed by the superintendent's office. He is liable for malpractice in the case of a minor, to the majority of the patient and whatever the statute of limitations may be beyond that; in one state to the age of 23.

In obtaining permission for necropsy the intern must get the signature of the right person, preference being given to the relative who assumes control of the body, bearing in mind that a minor cannot grant permission, though he is the sole survivor. One must be certain that the person granting permission clearly understands the nature of the necropsy and that the scope is definitely established, as well as understood and followed by the pathologist. Where the coroner system prevails one must be careful in doing autopsies on the orders of that officer. Limitations of his power exist and outraged relatives may cause difficulty. Every city has regulations as to what constitutes medicolegal or "medical examiners'" cases, including abortions, prisoners, wounds and deaths from criminal violence. Failure to report such may be serious for the hospital.

The house officer is amenable to the law and held for his acts in privileged communications in the same way as physicians in private practice. He is forbidden to communicate with patients for the purpose of engaging the services of attorneys.[1] He is forbidden to report deaths to or recommend particular undertakers. He may be summoned to court with hospital records and compelled to testify to facts. Interns must respond to subpena, but hospitals may and sometimes do refuse to disclose the names of members of the house staff who have treated patients involved in lawsuits, because much time is lost in attending court. The New York law is so comprehensive that the intern had best avoid all relations with attorneys except as the superintendent of the institution directs.

An intern at a charity hospital referred accident cases which he had solicited to two attorneys. Although he denied an agreement, he fully expected to be paid. He was advised to plead guilty to the charge and was sentenced to three months in the penitentiary (297 N. Y. S. 103[2]). He is subject to the national and state income tax laws. The superintendent of the hospital returns to the tax authority each year the list of employees having a minimum income, with board and living, if furnished, computed at approximately $500 a year.[3]

2. Cited by Hayt and Hayt.[1]
3. Hayt and Hayt: Legal Aspects of Hospital Practice, p. 15.

Many hospitals are getting a larger number of personal injury, street accident and compensation cases than ever before. Larger numbers of citizens come within the categories covered by various types of protection. The intern will treat many more of these cases in a short service than the private physician. The hospital should therefore have a clearly defined routine for his guidance, since the payment of the hospital bill and the patient's chances of financial recovery depend so much on prompt and proper reporting.

INTERNS' COUNCILS

The national Wagner act and the little Wagner acts of the states bring the place of the intern as an employee to the serious consideration of hospital authorities. Interns' councils, formed for scientific purposes for the maintenance of standards, should not be the cells for labor agitation. Demands for higher salaries have disturbed thoughtful physicians interested in fostering the spirit of true hippocratic medicine and loyalty to the ideals of the past. Criticism has been heard of breaking of contracts by interns without much consideration for the hospital.

It is unfortunate that social legislation compels the hospital to place the intern in the category of employees. "An employee is one whose duties consist in the rendition of prescribed services and not the accomplishment of specific objects, and whose services are continuous, not occasional or temporary." [4]

For compensation purposes the intern is covered by the law governing employees. Interns and nurses in a hospital maintained by municipal or other political units are also within the compensation law coverage. In a case of voluntary insurance by a charitable trust an intern is also held to be an employee.[1] An intern in the Cook County Hospital contracted epidemic meningitis and died. An award to his widow by the arbitrator was set aside by the industrial commission but it was affirmed by the circuit court and by the Supreme Court of Illinois. "A distinction is drawn between the position of a visiting or consulting physician and that of an intern, who has placed his time and service at the call of a superior. The intern is under a duty to spend his days and nights at the hospital, and to render any service, administrative or medical, exacted by the hospital through its administrative agents, within the range prescribed by propriety and custom. He is a servant or employee by every test of permanence of duty, intimacy of contact, and fulness of subjection." [5] When the Social Security Act is extended to include hospitals, the house officer will doubtless be included in its coverage.

LIMITS OF RESPONSIBILITY

No general doctrine exists fixing the limits of responsibility of different types of hospitals and the different classes of persons attached to the hospitals. Court decisions vary from state to state. House officers, along with pathologists and roentgenologists as well as private physicians and special duty nurses, are classed as nonadministrative employees. The general rule is that the hospital is not liable for their negligence. Administrative employees, all those attached to the superintendent's office, for instance, form the other group. Responsibility for their conduct may rest on the hospital, a knotty problem which the courts have considered for years.

The policy of today seems based on the acceptance of the fact that the hospital is not liable for the negligence of its doctors and nurses in any matter included in the patient's "medical care and attention." In some cases in which an operation is performed the intern, as well as the nurses, has been held to be the delegate of the surgeon, to whose orders he is subject. This includes the preparation for the operation. In the alleged performance of an operation without the consent of the patient, this was the opinion of the court. The fact that the house physician acts under the orders of his superior, who is a licensed practitioner, does not relieve him of responsibility. "The surgeon who performs an operation is not responsible for the acts of his assistants and nurses unless they are his own employees." So, the house surgeon who works with him cannot look to the chief for protection.

The doctrine is widely accepted that a hospital is not responsible for the acts of its visiting staff. The hospital undertakes to provide for the patient the services of its house staff. It does not promise to perform these services itself. The charitable hospital is relieved from responsibility for the acts of its employees provided it has not been negligent in its choice of employees. On the other hand, ". . . a hospital conducted for private gain is liable in damages to patients for injuries resulting from negligence of the nurses and employees. A patient is admitted to a hospital conducted for private gain under either an express or implied obligation that he receive such reasonable care and attention for his safety as his mental and physical condition, if known, may require" (*Meridan Sanatorium* v. *Scruggs*, 83 So. 532).

Under Wisconsin law a charitable hospital is to be regarded as exempt from liability to a patient for the negligence of its chief administrative officer in selecting employees who are either incompetent or negligent and also for the negligence of such employees in administering to the needs of the patient (*Morrison* v. *Henke*, 165 Wisconsin 166, 160 N. W. 173).

Though the private hospital has been held responsible for the negligence or tortious acts of its employees, nurses, house staff, the charitable hospital, since the case of *MacDonald* v. *Massachusetts General Hospital* (120 Mass. 432) of 1876 has been, practically throughout the country, freed of this responsibility unless negligence in the employment of its servants was shown; but in *Glavin* v. *Rhode Island Hospital* (12 R. I. 411), in which the patient brought suit for the alleged malpractice of an intern, the court rejected this doctrine. "Where there is a duty, there is prima facie, at least, liability for its neglect, that when a corporation . . . is created for certain purposes which cannot be exercised without the exercise of care and skill, it becomes the duty of the corporation . . . to exercise such care and skill, and the fact that it acts gratuitously . . . will not exempt it from liability for any neglect of duty . . ." It is understood that the legislature of Rhode Island saw fit to exempt the hospital from liability. But the intern whose alleged malpractice was the basis of the suit is still open to attack.

Ever since 1846, when the theory of absolute immunity of the charitable institution resting on its "trust funds" was enunciated, down to the present time many court decisions have been handed down. Other states have accepted decisions of the New York State courts in large part. Confusion has resulted largely because there has been no movement by those most interested to clarify matters by legislative enactment.

"Instability of economic conditions, especially within the last ten years, has greatly altered and visibly changed the mental reactions of the average individual within our community. Particularly in the larger population centers the older, confidential and trusted relationship between the physician and his patient has given way to habits of medical shopping. There has been an increasing tendency to seek legal redress through malpractice claims. This has affected both the medical practitioner and the hospitals. The rise of more universal use of insurance for health, for accident liability and compensation, has also disturbed the management of hospitals to no small degree. It has stimulated greed in certain groups of individuals and has resulted in attempts to abuse both medical and hospital facilities through sharp practice. The hospital's stand must at all times be one of equity and this is often rendered difficult." [6]

Relief of illness, teaching and research comprise the functions of the hospital. Devotion to these has kept trustees, administrators and staff from adopting the methods of big business. They have not been active in legislation. When disputes arise, specific charges of negligence end in another court decision. The definition of the basic rights, duties and obligations of the patient, the hospital house staff and visiting staff are not defined by statute law. And it would appear that the majority of hospitals are exempted from liability for the acts of its interns, and the visiting staff members may not be responsible. The great danger is that the intern may be the most exposed of all those attached to the hospital.

6. Hayt and Hayt: Legal Aspects of Hospital Practice, p. x.

INTERNS AND LICENSURE

The physician is, quite properly, completely absorbed in healing the sick and, if he is fortunate, doing his bit in improving the practice of medicine. He is interested in practical methods for helping the underprivileged. He is loyal to his patients and they apparently are to him. He is rarely interested in legislation or politics. When he receives a communication from a lawyer making a claim against him the doctor stands aghast. He cannot believe that any patient can be responsible for this, to him, outrageous attack. The practice of the courts is a dread and a mystery; they hold no allure for him. On the other hand, accustomed to direct action, he feels that their methods are cumbersome, wasteful and inefficient.

No uniform policy for limited licensure or exemption of interns from provisions of the law exists in the various state enactments. Thirty-six states practically ignore the medical student and the intern. Sixteen states have statutory provision, most of them being exceptions to the application of the medical practice act. In a few states the intern and/or the medical student is affirmatively permitted to practice medicine in a hospital under the guidance of teachers. Apparently, Massachusetts alone grants "limited registration" for the definite period of his internship (section 9A ch. 112) on completion of three and one-half years of medical study in approved schools. The state also grants a limited license to (section 9A ch. 112) "assistants in medicine who are under supervision of an instructor," students who have completed at least two years in medical school. Limitations are placed on the activities of such students, and the hospital and the other institutions to which they are attached under the direction of staff members. For the period of his limited registration the intern is permitted to sign birth and death certificates.

New Hampshire permits "resident physicians" to practice in any legally incorporated hospital. This is not wholly satisfactory, since no report of appointment is required of the "resident" or the hospital. Supervision cannot be exercised by the board of registration. Physicians ineligible for registration may become, for an indefinite period, whole time members of the staff of such institutions as the state tuberculosis

sanatorium or the hospital for mental diseases without compliance with the medical act. A lenient attitude is shown interns apparently by boards of registration out of consideration for the financial position of these young men, many of whom do not intend to locate in the state. All of them are known to be under the supervision of mature staff members, who with the hospital are presumed to be responsible for the conduct of house officers.

But should the intern as an unlicensed physician be charged with malpractice he is indeed vulnerable and his defense is handicapped. The attorney for the plaintiff emphasizes the illegality of his action. In addition to the charge of professional misconduct he is charged with crime. In some instances in which the hospital has been freed from the charge of negligence the intern himself has been charged with the same offense. In those states where the internship service is demanded for licensure the decision of a Wisconsin court is pertinent:

> It cannot be said that the performance of the duties with which it was alleged the defendants were charged were duties that it would have been lawful for them to perform. The law recognizes that a hospital internship of at least twelve months is required before a license to practice medicine may be granted. Although under the law no person may practice medicine, or hold himself out as authorized to practice medicine, without first securing the required license or certificate, yet the law itself requires an internship as a part of one's medical education before one can be licensed to practice. This is a legal sanction of the performance of such duties on the part of interns as are usually and ordinarily performed by them. The performance of such duties does not constitute the practice of medicine or a representation that the intern is authorized to practice medicine.[7]

A widely quoted decision of the New York Court of Appeals (*Hendrickson* v. *Hodkin et al.*, 276 N. Y. 252, 11 N. E. [2 D] 899) sets a precedent for possible court decisions making a hospital liable for the practice of any person not licensed by the state authorities.

MALPRACTICE

Malpractice is a distasteful subject. But it is an important subject, and if the experience of the recent past is to be that of the future it will demand more consideration. Hospitals with their trustees, staff, nurses and employees as well as private practitioners are all involved. No hospital is immune to the charge and there is no person concerned with medical care of patients in the hospital who is not liable to attack. House officers have been made defendants in actions for malpractice to the point that serious consideration should be given to means for their protection. A recent case, involving assault because of lack of a state certificate, and malpractice as well, required the united efforts of counsel for the hospital and attorneys for the state medical society to free the accused.

Nearly all suits for alleged malpractice end in a verdict for the defendant, but the effects of inevitable publicity faced by the house officer, the sense of unjust persecution can but injure the morale of any young man, whose career may be terminated then and there. Practically never is lack of knowledge the basis of complaint. Those interested in this subject feel that malpractice claims are increasing. Certainly suits against hospitals are common enough. Modern social philosophy demands security for the individual without his own responsibility for himself. The facility with which insurance can be purchased for almost every contingency, the widespread knowledge that almost everybody is insured, leads to unusual demands for satisfaction by the injured. It is no longer possible for the injured to be the cause of his own accident, and the law of contributory negligence has nearly ceased to operate.

It is a fact that some hospitals are understaffed, and interns, some routine administrative work being essential, may be hurried or become careless or, because of fatigue, make the fatal slip in technic or the thoughtless remark that leads to trouble. Sufficient oversight by the staff and relief from some routine will prevent such errors. To the ward patient the intern is the patient's doctor, coming closer, by far, to the man or woman than the chief visiting surgeon. We cannot forget that.

It may be argued that the chances for malpractice suits involving the intern are rare. But the slight yet perceptible increase in this sort of litigation, and the eagerness of attorneys for business, do not increase the safety of the intern. Such cases, like many others taken on a contingent fee basis, possess a nuisance value at least. Some settlement, however small, must be made, or one must face the alternative of expensive litigation. Attention should be directed to the evolution of some scheme for protection of the intern from attack.

CONCLUSION

From this study one may conclude that the exact status of the intern has not been established. To his medical school he may be a student or an alumnus, to the hospital an officer or an employee or an independent contractor (private opinion of attorney), to the state a student or a physician either licensed or unlicensed. With the change in our concept of the internship as an essential part of the education of the physician with gradual standardization of the state requirements for the practice of medicine, with the increasing emphasis on longer hospital training, the status of the entire house staff should be definitely established.

7. Medicolegal Cases: Abstracts of Court Decisions of Medicolegal Interest 1931-1935, Chicago, American Medical Association, 1936, p. 257.

The house officer should have the protection of the law and certainly the moral protection of the hospital and organized medicine. State boards of registration should either demand registration before internship or grant exemption from the requirements of the medical practice act. Suits for malpractice having a serious effect on the future of these young men should be prevented. It is a matter of concern for us all.

The contribution of the members of the Federation of State Medical Boards might well be, where it is lacking, a legalizing of the position of the intern, for the protection of the man himself and the hospital he serves. The grant of a temporary certificate as provided in the Massachusetts law would remove much of his handicap.

Brown House.

Comments and Reviews

CONCERNING INTERNS AND INTERNSHIPS

Abridgment of an article by Reginald Fitz, Wade Professor of Medicine, Boston University School of Medicine, and published in the Journal of the Association of American Medical Colleges, March 1939.

There regularly develops in medical schools at the end of the third year, or early in the fourth year, an epidemic of worry over internships. This seems a pity, because the clinical work should not be interrupted by extraneous factors.

From two successive surveys of the Massachusetts interns and internships, it is apparent that our internships are regarded as useful and that our interns, in general, are promising young men. The better students select our better teaching hospitals in which to be trained; on the whole, the better the internship offered, the better is the scholastic record of the intern who is accepted; the weaker hospitals which offer the poorest training attract the poorest students.

Not all of the best scholars in the Boston schools care to remain in Massachusetts for their internships; in fact, some of our best students prefer to go to other parts of the country for intern training. To make up for their loss, we attract graduates from other schools. On the whole, this also is satisfactory. The men from outside schools, as a general rule, are acceptable and stimulating scholars, so that to have them wish to come to Massachusetts is a feather in our cap.

A situation has arisen, however, which is not so pleasant. Hospitals naturally wish to attract to themselves the best possible interns they can get, and to do this they appear to vie with one another in making their appointments at earlier dates than do their competitors.

For many years the Boston teaching hospitals have held examinations for interns on or about January first. A number of hospitals outside Boston were written to for information concerning the date at which their 1939 appointments will be made to include candidates who will not graduate until June. Twenty-three hospitals have replied to this letter. Each of these hospitals can safely be guaranteed to any student as offering as good an internship as is obtainable in the United States. In most instances they represent teaching hospitals in various parts of the country which are in the habit of drawing away from Massachusetts fourth year student material of the highest caliber. These hospitals make their appointments as early as November (two hospitals), early in December (five hospitals), and mostly during the Christmas holidays, a time which appears to be convenient for personal interviews between hospital and applicant to take place.

Thirty-nine hospitals in New England approved for intern training, but not strictly allied with medical schools, also replied to the letter. In this group the answers were particularly interesting. One hospital is so forehanded as to make intern appointments in July for men who will not graduate until the following June. Another makes its appointments in September, one in October, one in November, many in December, and only a comparative handful after the first of the year. One excellent hospital wrote, very honestly, "In years past we have always made our appointments on or about February 15, but from our experience of the past year we found that many of the applicants for our internships canceled their applications and some even canceled their appointments which they have received because they had accepted appointments in hospitals elsewhere. It is our feeling that we should make our appointments this year not later than January 1. We wish that there might be some way that the intern committees serving the various hospitals could come to a definite understanding as to the date of appointment for interns."

COMPETITION FOR INTERNS

Medical schools in other parts of the country wish that such ardent competition for interns as now exists could be done away with and that intern committees serving the various hospitals could come to a definite understanding as to a uniform date of appointment for interns.

Nor is the problem a new one. Thirty years ago a representative hospital, such as the Massachusetts General Hospital, held its examination for interns in the early spring. Little by little, however, as the importance of internships was universally acknowledged and as the competition for interns grew keener, the date of examination for the Massachusetts General Hospital was pushed back closer to the beginning of the fourth year in order to keep in step with what other hospitals were doing. This method of approach to the situation was not effectual. All that happened was that other hospitals pushed their examinations even further ahead.

Finally, medical students themselves began to complain of what was happening. In 1937 Victor Richards, a junior in the Stanford University School of Medicine, published an interesting paper entitled "The Internship," giving an undergraduate's point of view on the matter.

Nearly a year ago the third year classes of the Harvard Medical School and of Tufts Medical College wrote letters to the Boston Committee suggesting, in effect, that it would be highly desirable from these students' point of view if some arrangement could be established by which intern appointments could be made in various hospitals at about the same time, thus to "avoid the complications and duplications heretofore experienced."

Thus, it is apparent that medical schools, hospitals and students all dislike the present confusion and feeling of competition regarding intern appointments. Some sort of a reform is badly needed.

DESIRABILITY OF A REASONABLE TIME SCHEDULE

As to what can be done and how to do it is more difficult to say. Boston has made efforts, sporadically, to have its examinations for interns in the teaching hospitals come at the same time as do the examinations for interns in other teaching centers. This effort has never met with any wholehearted support, chiefly because each hospital is apt to desire a personal interview with prospective interns and it is practically impossible to work out a reasonable time schedule that will suit every one. The Intern Placement Bureau of the Association of American Medical Colleges is playing a helpful part in the matter, and as the bureau develops its scope it may become even more useful. Fundamentally, however, in Boston we feel that, since hospitals, students and medical schools recognize the evils of the present way of doing things, the reason that these evils have not been corrected must depend on lack of positive leadership and a lack of any well defined, broad policy.

If the schools would agree to give out no information regarding any student's abilities to any hospital before a certain date to be agreed on, part of the more ruthless competitive methods now in use for attracting interns might be done away with. And if the hospitals would live up to an agreement not to examine intern candidates or to make intern appointments before a date to be set by the American Hospital Association, the matter would be still further clarified. Finally, it might be possible for the teaching hospitals to combine examinations in some manner and to interchange candidates, thus doing away with unnecessary examinations and traveling on the part of students.

THE HIGH ROAD

Abridgment of an address by Dr. Howard T. Karsner, professor of pathology, delivered at the commencement exercises, Western Reserve University School of Medicine, June 15, 1938, and published in the Clinical Bulletin of the University Hospitals of Cleveland, September 1938.

Ordinarily a long life may be expected to have furnished equanimity and wisdom. Add to this a life in a laboratory, secluded from the bewilderments and hurly-burly of competitive efforts in the world of affairs, with time for meditation and leisure, the setting is right for an outlook of wide perspective. If that laboratory man happens to be a pathologist, his hands stretch out on one side to the so-called nonclinical divisions and on the other to the glamorous clinics. He may be not much of a scientist and nothing of a clinician, but he has an acquaintance with both and he usually thinks his field gives him privileges in the way of liberal interpretations.

What can he say to those who are ready to enter the fields of practice? Can he give advice about the details of practice and, if he could, would his recommendations have concrete value? What can he say about the specialties and the specialists? Can he dilate on the confused state of world affairs? Tempting as these questions are, this occasion gives me the opportunity to speak of broader principles in the hope that they will offer guidance to the high road to a happy life spent in service of one's fellow men.

This is said in no spirit of abstruse altruism. It refers rather to the adventures of that scientific pursuit which, by the selection of a career, students have laid out for themselves. Full of interest in its daily work with patients, exciting in its new discoveries, enlightening in its contacts with the phenomena of nature, revealing in its study of mind and matter, consoling in its successful results and tragic in its failures, this calling of ours has spiritual rewards not to be equaled in any other profession.

The distinguished members of our profession all have put something more into their work than their less noteworthy colleagues. To be sure they have an aptitude, a gift, a flair for the

task, they have had good fortune from time to time, but they have applied themselves incessantly to attain success and, above all, they have believed in and loved the job they chose. Claude Bernard once said "We stand upon the intellectual shoulders of those medical giants of bygone days and, because of the help they afford us, we are able to see a little more clearly than they were able to do."

There are features of our profession which deserve particular thought. First, some comment about the case as a patient. You have devoted the major part of four years to becoming competent to determine the disease from which the patient is suffering and the means of managing it intelligently. This training will always be a considerable part of your psyche and this foundation must ever be refreshed, extended and deepened. Go to meetings, read the journals, discuss with your associates, attend graduate courses but, after all, the continuation of your own initiative and progress depends on an inquiring and critical intelligence which never falters. Thus you can improve your knowledge of organic disease, without which you lose dignity as a physician and become little more than a pedler of pills. If your attention is confined to diagnosis and treatment you may know much about disease but little about the patient. This has often been spoken of as a difference between the science and the art of medicine. It is no art to be well aware of the social and psychologic implications of illness, nor is it an art to be so devoted to the welfare of your patient that with sympathy and consideration you will aid him in his necessary adjustments. It is not an art to be human and humane. These are inherent qualities of that spirit which has called you into the field of medicine. No courses in medical schools are necessary for kindly, generous and thoughtful consideration of those frailties of human nature which often alter personality when illness strikes. There are, however, dangers in sympathy. The physician must guard against allowing his feelings to overcome his judgment. Thus, in order to carry on successfully, a balance must be attained between sympathy and calm appraisal of the situation. If the doctor can assure himself that his diagnosis is correct and his treatment appropriate, he can await the outcome with poise and equanimity which are essential to him and to the welfare of his patient.

SO-CALLED IMAGINARY ILLNESSES

In your courses of instruction you have dealt largely with disease as expressed by organic disturbances. You have given consideration also to the personal aspects of disease but you probably have paid little attention to what are often thoughtlessly called imaginary illnesses. If this is true I desire to remind you that in the practice of medicine you will be repeatedly confronted by patients with this sort of disturbance. You may easily become impatient with patients' complaints for which, even after the most careful examination, you can find no organic basis. You may be tempted often to dismiss the matter and the patient with the comment that there is nothing wrong or you may resort to some more or less shady method to shock him out of his beliefs. This may be effective, but only temporarily. Psychoneurosis is a real disease, even though you may not find an organic basis. The headache from which the psychoneurotic suffers is headache, his pain is genuine, his vomiting is not imaginary. His incapacity is an economic problem and his suffering cannot be alleviated by telling him there is nothing wrong. The child who was blind because a firecracker exploded near him was unable to see even if his eyes were normal. The boy who could not swallow was really emaciated even though his esophagus was perfect. The woman bedridden for years was an invalid in spite of the fact that her spine was unaffected. This disease does not spare man, woman or child, rich or poor; even if its basis is emotional, that in itself is fact. It is your duty to find the reason for this disturbance and to teach or reeducate your patient to adapt himself to his environment, to adjust himself to his limitations, to make himself at peace with the world. The meaning of the word doctor is teacher and it can have no better exemplification than in the management of the psychoneurotic. If the general practitioner cannot care for the patient he must not turn him away but refer him to one who by temperament and training can. This course is more than the treatment of the current attack. When properly carried out it gives the patient a new outlook, it trains him to be dependent on himself and thus prevents recurrence or new manifestations. This whole problem presses on all branches of medicine. You cannot avoid its consideration by saying that you will ultimately specialize, for all those who practice in whatever specialty must deal with the problem.

RATIONAL PSYCHOTHERAPY

This aspect of practice is more important than your individual success. Its neglect by physicians has had as much to do with exploitation by the cultists as any other factor in society. The responsibility for the upbuilding of the cults rests largely on the shoulders of your predecessors who have neglected the psychoneurotic, and the cults will continue to grow if you fail in your duty to your patients and your profession. If we in medicine were to recognize the merits of rational psychotherapy and utilize it, we would not be subject to the humiliation of having our friends and patients cured by a

twist of the foot or a travestied verse from the Bible, nor need we resort to these tricks. We cannot comfort ourselves that this quackery appeals only to the unintelligent, for we know well educated, fine people who voluntarily subject themselves to it. The reason behind this is often that the doctor has failed in his job. He has neglected psychoneuroses and has left the patient to his own resources. The patient, unfamiliar with the nature of or reason for his illness, then turns to some one who will help him. It is no reflection on his education or intelligence that he does not know what ails him. His doctor has failed him and he still needs help. The personality and salesmanship of the quack are ready substitutes for appropriate medical care. What we need is to fulfil our function as teachers. We have our faults, we shall make errors, we shall find that new discoveries make our older methods obsolete, we shall learn that truth is only relative. In spite of failures we can point with pride to our progress. With continued study, widening experience, careful observation and sound logic our successes become proportionately greater. Let us be true to our calling and earn the tranquillity that loyalty engenders. Go forth on the road and follow it to the heights. I wish you all success and happiness.

PHYSICAL FITNESS AT UNIVERSITIES

Abridgment of a discussion published in Nature, May 14, 1938. It refers especially to universities in England.

Those Englishmen who are acquainted with the universities of Canada and the United States have long had cause for astonishment at the way in which the universities of Great Britain have lagged behind those of America in their care for the health and fitness of their students. In those countries at any rate it cannot be suggested that the desire to produce a healthy population is a sign of latent militarism or of any peculiar brand of politics. To an American or Canadian student—or professor—visiting Great Britain it seems incredible that in most universities there is no medical examination whatever, either at entry or later on, no organized system (voluntary or compulsory) of physical exercise, little provision (except in a few privileged places) for healthy recreation "in the spare half-hour," no arrangement to provide medical or surgical advice or treatment when required.

The causes of this neglect are various and to some degree, at least, a matter for speculation: the medieval view, based on a false antithesis of mind and body, that the universities exist solely for the training of the intellect; a superstitious horror of anything which might savor of organization, discipline or compulsion in personal affairs; a belief in the magic of laissez-faire; the dominant position in public life of Oxford and Cambridge, where the colleges exert a parental influence, where most of the students are not so poor, and where games and recreations are much easier to get; indifference; a fear that students themselves might not cooperate. The last cause at least is removed by the publication of a pamphlet[1] on behalf of the students themselves. It is peculiarly timely because, unknown to its writers, a new movement was already under way and that movement will be given greater confidence and strength by the knowledge that the National Union of Students is openly and emphatically sympathetic. The committee of the union which discussed the matter "was struck with the fantastic lack of attention there had been in this country to scientific methods of physical education. . . . It became more and more impressed with the importance of preventive as well as curative methods." The systems in other countries, it found, "indicate a very general acceptance by the universities of a great measure of responsibility for the physical as well as the intellectual well-being of their students, a responsibility which is still to a large extent shirked by the universities of Great Britain."

FACILITIES FOR RECREATION

In the autumn of 1937 the National Fitness Councils for England and Wales and for Scotland invited the University Grants Committee to advise on the distribution of a capital sum of £230,000 to aid the universities of Great Britain in providing urgently needed facilities for healthy recreation and for physical exercise. The sum itself is small—only about one tenth of the annual Treasury grant, for all purposes, to the universities—and it can do no more (it was not intended to do more) than catalyze the interest of the universities themselves and perhaps of their potential benefactors. That, however, it is beginning to do, and although the £230,000 itself cannot be spent otherwise than on facilities for healthy recreation—on gymnasiums, swimming baths, squash courts and the like—it has set the universities thinking and planning, and ultimately very much more may result. In most of them, indeed if not all, voluntary medical examinations are to be instituted, lectures will doubtless be given on matters relating to health, the status of members of the staff dealing with physical training is to be raised, the cooperation of scientific and medical departments is to be sought, committees are to be formed to consider the place of student health as a proper function of a university and probably, under the guidance of the Medical

1. Student Health: Report of an Enquiry into University Health Services by the National Union of Students, London, National Union of Students, 1938.

Research Council in certain special centers, a scientific examination of the problem is to be instituted. An attempt is to be made in fact to give to the subject of bodily and mental health and fitness its proper university status. Those, however, who take a longer view will realize that it is not merely "student health" as such which is to be aimed at but, through the universities, the intelligent and conscious application of a new biologic outlook on human beings, an outlook intended ultimately to affect the entire community.

To recognize disease, minor ailments, chronic undernutrition, mental trouble or anything lowering the level of happiness, fitness and usefulness in university students, and to provide means of improvement, are important enough. Even more important, however, in the long run is to send out steadily into the community a stream of intelligent and keen young people who have learned, even in a minor way, what a health service can do for them and their friends. and how necessary it is to the happiness and well-being of the people.

ACHIEVEMENTS OF STUDENT COUNCIL

The Student Council at Wayne University College of Medicine, Detroit, has matured as a competent student self-government body, said the dean, Dr. Raymond B. Allen, in his recent annual report. Among its noteworthy achievements have been the establishment and successful administration of an honor system for the conduct of examinations in the college, the publication of the student-alumni journal, which is entering its second successful year, the publication of a student handbook, the creation of an interfraternity council, the establishment of a local chapter of the National Association of Medical Students and the institution of student-faculty-alumni banquets, which have served as an active socializing influence for all three groups and have helped to develop an *esprit de corps* and pride in the school without which the work of the faculty would be without real value.

Another significant contribution of the Student Council has been its analysis of student questionnaires which solicited constructive criticism on the medical curriculum. This study clearly indicates that the students recognize the importance and value of sound fundamental training in the medical sciences. Suggestions have been forthcoming which have helped to improve the effectiveness of the teaching program. The faculty recognizes that students are not competent to pass on the content of the medical curriculum, but it appreciates that students are in a position to know whether or not the faculty efforts are effective in attaining educational objectives.

One aspect of the Student Council's study relates to the economic status of the students. Inquiry was made into the outside activities of students which of necessity detract from their ability to apply themselves to medical studies. The council was not surprised to find that a large proportion of the students support themselves entirely or in part through gainful employment. Some students hold eight hour night positions in industry. The majority of these, however, are engaged in some form of medical service, usually in the nature of first aid posts in industrial plants. Fortunately, such duties are not arduous and serve in some ways to promote rather than hinder their medical education. However, it is perfectly clear, Dean Allen said, that a large fraction of students do not receive sufficient financial support to be in a position to gain the greatest possible benefit from their studies. This study, therefore, indicates that means must be found for furthering the security of deserving, needy students. The board of education and the alumni association of the college of medicine have, through loan funds, rendered great help in the neediest of cases. Many students, however, are reluctant to go into debt for their medical education and do so only in the greatest extremity, usually to meet tuition fees. The solution is obvious: scholarships should be available for students who have proved their right to such subsidy. Some aid is rendered through the National Youth Administration and through student assistantships. These devices, however, are not to be encouraged for the reason that the student is required to give time which he would otherwise be devoting to his studies.

Interest in Civic Affairs

It is just as important that physicians be made social conscious as it is that the public be made health conscious. This can be brought about effectively by emphasis on the community aspects of medicine both in the medical school and after graduation. Such a study and social interest on the part of the medical profession will insure its rightful heritage of preserving the health of the public and supervision of all forces engaged, for four reasons: First, it will stimulate the young physician to take an active interest in civic affairs, and to seek and accept public positions for which his training makes him especially adapted. He will thus become more familiar with the social and medical status of his community, and sympathetic with and interpret the needs of the man of the street. Secondly, it will give the physician a better understanding of the factors which may have lowered the patient's resistance and apply appropriate measures to remove them. It is generally recognized that a patient's mental attitude often has a great influence on the course of a disease. Social and economic conditions directly affect the mental status of the patient and are often, therefore, of prime importance in dealing with his disease.—Wahl, H. R.: Community Aspects of Medicine, *J. A. Am. M. Coll.* **13**:14 (Jan.) 1938.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Student Book Exchange at Michigan

The Board of Regents of the University of Michigan, Ann Arbor, at a meeting in December, gave permission for the establishment of a Student Book Exchange at the university on condition that only used books would be handled. A committee was formed comprising the dean of students, the dean of women, and representatives of the Michigan Union and the Michigan League to direct the venture. The exchange operated for the first time February 3-17 and sold books to about 2,000 students. About 1,700 students left books to be sold, setting the price that they wished to receive, with the understanding that the exchange would retain 10 per cent of the sale price to cover expenses. The next sale of used books will be in September, for which books will be received in the exchange as early as June.

New Division of Bronchoscopy

A division of bronchoscopy and esophagoscopy is being organized at Louisiana State University Medical Center, New Orleans, in anticipation of the opening of the new Charity Hospital, which will contain a fully equipped unit provided with biplane fluoroscope and similar equipment. Dr. George J. Taquino will be in charge of the division in the medical school, the staff to consist of members of the department of surgery and the division of otorhinolaryngology. Dr. Chevalier Jackson, Philadelphia, has been visiting professor of bronchoscopy and esophagoscopy at the medical center since it was opened in 1931.

Banquet for Premedical Students

The fifth annual banquet for premedical students throughout Texas was held recently under the sponsorship of the Texas Alpha chapter of Alpha Epsilon Delta. Dr. John W. Spies, dean, University of Texas School of Medicine, Galveston, was toastmaster; the speakers were Drs. Holman Taylor, Fort Worth, secretary of the Texas State Medical Association, and Dr. William R. Houston, Austin. Seven colleges were represented by 364 premedical students.

Dr. Lapham Appointed Dean at Tulane

The president of Tulane University has announced the appointment of Dr. Maxwell E. Lapham as dean-elect of the school of medicine of the university to succeed Dr. Charles C. Bass in 1940. In that year Dr. Bass will reach the retiring age.

Dr. Lapham, now 39, was born in New York and graduated from the University of Pennsylvania School of Medicine in 1925, following which he served two years as an intern at the Presbyterian Hospital, Philadelphia, and then was house surgeon at the International Grenfell Hospital in Labrador. He was a resident in the University Hospital, Philadelphia, for two years and then engaged in the private practice of medicine for three years. In 1933 Dr. Lapham took up graduate medical extension teaching, giving courses of instruction to practicing physicians throughout the state of Virginia under the auspices of the University of Virginia and in cooperation with the Virginia State Medical Society and the Medical College of Virginia. Later for two years he gave extension courses in obstetrics to practitioners in Mississippi in cooperation with the Mississippi State Health Department, the Mississippi State Medical Society and Tulane University.

In 1937 Dr. Lapham was appointed director of the extension division of the department of graduate medical studies at Tulane. He will continue in this capacity for several months, as well as in his work as assistant professor of obstetrics and in the fall he will undertake a tour of the medical schools in this country and in some foreign countries.

Examinations for Internships in Naval Hospitals

An examination is held in November each year for senior medical students of class A medical schools who desire to obtain an internship in one of the United States naval hospitals. Senior medical students who qualify for appointment to an internship will be appointed acting assistant surgeons with rank of Lieutenant (junior grade) for temporary service during the intern year. On satisfactory completion of the internship, the intern will be allowed to appear for competitive examination for appointment as assistant surgeon with the rank of Lieutenant (junior grade) in the medical corps of the navy. Should the intern desire to return to the practice of medicine in civil life, his appointment as an acting assistant surgeon will be terminated and he will be honorably discharged from the naval service. To be commissioned in the medical corps of the navy the candidate must be a citizen of the United States between 21 and 32 years of age and he must pass both professional and physical examinations. On accepting an appointment as acting assistant surgeon for internship, the officer will receive a compensation of $2,699 a year if he has no dependents, and $3,158 a year if he has dependents. Successful candidates for appointment as interns will be appointed in July and will be assigned for internship to a naval hospital either in Boston, New York, Philadelphia, Washington, D. C., Norfolk, Va., San Diego, Calif., or Mare Island, Calif. The period of internship is one year, is rotating and consists of about five months medical, five months surgical and two months laboratory duties. For additional information address the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Harvard Extends Its Public Service

Extension of the public service of the Harvard Medical School in Boston through the newly formed department of legal medicine was announced January 5 by the dean in his annual report. Dr. Alan R. Moritz, after another year in Europe, will return to build up the department of legal medicine and to put at the disposal of the state the contributions that such a department can make to problems of law enforcement and of public health which come within its scope. Dr. Moritz came to Harvard from the University Hospitals, Cleveland, in 1937, to be the first holder of the professorship of legal medicine established under the terms of a gift designated as the George Burgess Magrath Endowment for Legal Medicine. He succeeds the late Dr. George Burgess Magrath, who taught legal medicine at Harvard from 1907 to 1937.

Dean C. Sidney Burwell said that the medical school has a direct and useful contribution to make to the community and that in turn it is dependent on many

community organizations for essential parts of its teaching opportunities.

The Harvard Medical School is associated with fourteen local hospitals through clinical teaching or investigation. A close coordination exists between the state department of public health, the department of public health of the city of Boston, similar departments in other cities, and appropriate departments of the medical school and school of public health. Thus the medical school is happily able to make some return to the community which supports it not only in training practitioners of medicine and investigators, Dean Burwell said, but in contributing to the care of the community's sick and to other aspects of community life where expert medical knowledge is useful.

The Wassermann Laboratory of the Massachusetts Public Health Department, established in 1909 by the Medical School, is still housed in Harvard buildings. The laboratory affords facilities for testing the blood and spinal fluid of patients in the state hospitals for mental disease. In 1917 the Massachusetts State Tumor Diagnosis Service was established as a joint activity of the Massachusetts Department of Health and the Collis P. Huntington Memorial Hospital of Harvard. This service supplies pathologic diagnostic service for physicians in the state and for hospitals without service of their own. Harvard Medical School also organized and established the Vaccine and Serum Laboratory at Forest Hills. For several years the Faculty of Medicine has arranged a series of public Sunday afternoon lectures on medical subjects at which last year the total attendance was more than 3,000.

Medical College of Virginia

The historic Egyptian Building at the Medical College of Virginia is being made fireproof; the remodeling will also provide an auditorium seating 400, done in the Egyptian manner. In the future the Egyptian Building will house the departments of pathology and bacteriology.——An eighteen story hospital to replace the Memorial and Dooley hospitals is under construction and should be ready for occupancy in the spring of 1940.——An additional floor which is being added to McGuire Hall will furnish medical facilities for the departments of physiology and pharmacology.——The new dormitory completed last July has been named Hunton Hall in honor of the late Eppa Hunton Jr., a member of the Board of Visitors for many years. These and other construction projects at the Medical College of Virginia will involve an expenditure of more than $2,000,000.

Yale Alumni Day

Special lectures, clinics, ward rounds, laboratory demonstrations and conferences were presented at Yale University School of Medicine, New Haven, Conn., February 22, in celebration of Alumni University Day. Guests were also invited to visit the laboratories and see the facilities of all departments of the school, including the Clinic of Child Development and Laboratories of Primate Biology. There were demonstrations of the ultracentrifuge, of the laminograph, of the bioelectrical potentials in living systems, of the apparatus for studying electrophysiology of the brain, of the heart sounds by loud speaker and of monkeys and chimpanzees with spinal and cerebral lesions. The day closed with an assembly in the auditorium of Sterling Hall of Medicine, which was addressed by Drs. Francis G. Blake on "Sulfapyridine in Pneumococcal Infections," Milton C. Winternitz on "The Pathology of Arteriosclerosis," Hugh M. Wilson on "Body Section Roentgenography," and by the dean, Stanhope Bayne-Jones, on "Plans for the Future of the School."

Ohio State Board Questions

Following are the questions used by the State Medical Board of Ohio in practice, Dec. 7, 8 and 9, 1938, at Columbus:

1. A patient returning from a late summer motor trip, complains of headache, diarrhea and slight fever of ten days' duration—what would you suspect and what other signs would you look for? How establish a diagnosis?
2. Give three possible terminations of arterial hypertension and upon what sign would you base the most probable in a given case?
3. Discuss undulant fever: the etiology, usual source in this country, symptoms and treatment.
4. Give the symptoms of suspected coronary occlusion and how to establish the diagnosis?
5. Give the symptoms of Addison's disease with treatment.
6. Give the usual etiology of enuresis and treatment.
7. How would you recognize pyloric stenosis in a recently born infant?
8. How would you manage a case of acute diarrhea in a 2 year old child?
9. Enumerate the most common symptoms of schizophrenia. Give the clinical course of a typical case.
10. Name the most frequent organic psychoses and state the most common mental symptoms characteristic of the entire group.

Convention of the Association of Medical Students

The third annual convention of the Association of Medical Students held in Philadelphia beginning Dec. 22, 1938, was attended by 303 delegates, of whom 279 were medical students and twenty-four were visitors, including one representative of the American Youth Congress; the women medical student delegates numbered thirty-eight. The delegates came from twenty-four states and the District of Columbia; India, Korea and Canada were also represented, while six premedical colleges sent representatives to learn about the Association of Medical Students. Twenty-three resolutions were passed at the business session. The program of this convention was published in the December Student Section in THE JOURNAL. Student Trawick H. Stubbs of Emory University Medical School, Atlanta, Ga., and Student David E. Hepford, Temple University Medical School, Philadelphia, were elected co-presidents of the association for this year.

Senior Students Tour Pharmaceutical Laboratories

The present seniors of Indiana University School of Medicine made a tour of inspection of the Eli Lilly & Co. pharmaceutical laboratories at Indianapolis recently and were guests at a luncheon at the laboratories and a dinner at the Hotel Severin. Dr. Clayton G. Weigand was the principal speaker; Dr. Willis D. Gatch, dean of the medical school, represented the students on the program. An annual tour of inspection of these laboratories has been made by each senior class for nearly twenty-five years.

Dinner to New Dean

Dr. William S. McEllroy, who was recently appointed dean of the University of Pittsburgh School of Medicine, was honored with a dinner at the Hotel Schenley March 1 by alumni of the school and friends. Dr. Charles H. Henninger, Pittsburgh, president-elect of the Medical Society of the State of Pennsylvania, was master of ceremonies, and addresses were made by Chancellor John G. Bowman, Dr. Alexander H. Colwell and Dr. McEllroy.

Annual Lecture at University of Colorado

The first annual Nu Sigma Nu lecture before the faculty and students of the University of Colorado School of Medicine, Denver, was delivered April 7 by Dr. Walter L. Palmer, associate professor of medicine at the School of Medicine of the Division of Biological Sciences, University of Chicago, whose subject was "Recent Advances in the Study of Gastric Disease."

COLLEGE EDUCATION FOR THE FUTURE DOCTOR

JAMES B. CONANT, PH.D.
President, Harvard University
CAMBRIDGE, MASS.

You will all remember the old definition of an expert as an ordinary man away from home giving advice. Although I am a fair distance from my academic base, I should like to think that I could qualify on other grounds as an expert on the subject that I am venturing to discuss this morning. What I have to say concerns premedical training and in a previous incarnation I spent a great deal of time with premedical students. I taught organic chemistry for some dozen or more years in the winter and in the summer to both men and women. I have written innumerable letters to many of the deans present in this audience, recommending in no uncertain terms people whom, I regret to state, I knew all too little about. Furthermore, I have taken part in innumerable discussions with other chemists from many colleges about educational matters and almost without fail the conversations turned to a discussion of some of the iniquities of the medical school admission committees. More recently I have had the opportunity of discussing educational matters with deans and college administrators and again the problem of the relation of medical schools to liberal arts colleges has repeatedly arisen.

According to statistics published a few years ago somewhat more than 50 per cent of the students entering the medical schools of the country complete a four year college course. Another 27 per cent finish three years of collegiate work. It is with these students who comprise about three quarters of the matriculants in our medical schools that I am concerned this morning. What sort of an education should these future doctors receive in college? It seems to me that we cannot answer this question in general terms. There probably are as many answers as there are students. But before we come to the difficult matter of prescribing for the future let us examine the present situation. Let us see how the premedical requirements of the various medical schools affect the present college education of the future doctor.

It is important to bear in mind that today there probably are two applicants for every position in a first year medical class. For certain of the schools, the ratio may run as high as ten to one. Certain effects of this competition I think have not been generally appreciated, though they are clearly evident to those teachers and administrators in our colleges who are concerned with premedical education. I have received testimony from many different colleges that the desire to present a convincing record of scientific work to impress the admission committee is a potent factor in determining a student's program. It is not a question of doing well in the minimum prescribed courses in chemistry, physics and biology. It is not a question of taking more science either as an educational discipline or because the student likes the work. It is merely a question of taking scientific courses solely to impress the medical school authorities.

I realize that officially almost every medical school is at pains to deny that any preference is given to candidates who have studied more than the minimum premedical subjects. I know that many deans, professors and members of the medical profession protest that what they all desire is a man with a liberal education—not a man who has been through four years loaded with premedical sciences. The trouble is very few people believe this group of distinguished witnesses —least of all the students. And since each case of acceptance or rejection of a candidate for admission to a medical school cannot be argued in open court and the decision of the committee duly publicized, misunderstandings and, indeed, fantastic rumors are bound to arise.

Now those who complain about the present situation (and their name is legion) are not necessarily opposed to a scientific course in a liberal arts college as a preparation for medicine. What they are opposed to is, first, what they believe to be the inconsistency between the theory and practice of the admission offices of the medical schools; second, the pressure on all students who want "to play safe" to take more than the minimum premedical requirements whether they are interested in science or not; and, third, the apparent failure of the medical schools to clarify their own desires with regard to even the minimum premedical requirements.

That there is some confusion in the medical faculties themselves in this matter of premedical requirements, I am sure this audience will agree. Part of the difficulty arises from the fact that the total professional training of a medical man must depend to some extent on his plans for the future. If he is to become a research worker in medical science he should study the fundamental sciences in considerable detail in college. If he is to be a general practitioner the minimum scientific premedical requirements may well suffice. Since this total professional training includes the college years, it is impossible to draw up blanket specifications for the college education of the future doctor without answering the question "What sort of a doctor is the man to be?"

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 13, 1939.

A rather amusing illustration of the present confusion of opinion in the medical profession concerning premedical studies was brought out by replies to a recent questionnaire sent to a small group by the dean of one of our large medical schools. Members of the faculty and eminent practitioners living nearby sent in long letters. I have taken the liberty of combining extracts from these documents in what I must admit is a highly arbitrary manner. I assure you that the general effect which the following synthesized statement leaves in the reader's mind is not a bit more confusing than the effect of reading all the letters in toto. Here is the composite opinion as to premedical requirements:

Good fundamental education in physics, biology, chemistry, zoology and comparative anatomy, he should have a reading knowledge of French and German . . . in addition to being well grounded in inorganic chemistry it would be desirable for the student to be well prepared in the elements of quantitative chemical procedures and in the laws governing the behavior of electrolytes in solution . . . The student's curriculum should include thorough courses in general zoology or general biology, comparative vertebrate anatomy and vertebrate embryology. The growing importance to the general physician of a knowledge of genetics makes a course in this subject very desirable . . . But it is to be hoped that the student would spend most of his time at college working in history, English and literature for the last chance most medical students have at any type of cultural courses is gone with the granting of the A.B. degree . . . [In summary] we would say that a student should bring with him to the medical school a fair degree of native intelligence, a fine character, an integrated personality and a training which has taught him the rudiments of the scientific manner of thinking . . . A modicum of factual knowledge in the special fields of chemistry and biology is also important.

The present situation is to say the least somewhat obscure. The difficulties of laying down one set of rules to cover the college education of all future doctors —even the scientific education—seems to be insurmountable. We are confronted with the fact that today the liberal arts colleges are expressing more and more dissatisfaction with the premedical requirements and the procedure of medical school admission committees. This dissatisfaction comes from presidents, deans and teachers of the humanities as well as from those directly concerned with teaching premedical subjects. What is to be done about it? I have heard only one concrete suggestion for a radical change that seems to me to offer hope. I venture to pass it on with enthusiasm, but without too much expectation that it will be accepted. The suggestion is as follows: Encourage college freshmen who are looking forward to a medical career to apply for admission to a medical school three years in advance. Let the admission committee base its rejection or conditional acceptance of such applications on the school record, on the first year college record, and on performance in such tests as the scholastic aptitude test. After the undergraduate in question has been tentatively enrolled as a future medical school student, let there be cooperation between the medical school and the college in working out through a joint committee an intelligent college program for the remaining three years. For those with a real scientific bent, concentration in chemistry or biology or a combination of the two may be in order. For others the main line of endeavor may be history or philosophy or literature with only the minimum amount of science. The program would be made to suit the student. The representatives of the medical faculty would have in mind the needs of the profession, and the representative of the college faculty would supply intimate knowledge of the student and the offerings of the institution in question. The joint committee should insist on every student's broadening out as much as possible during his college years. The fact that the medical school faculty was concerned with the college work of the premedical student would, I believe, lend an authoritative tone to any regulations which emphasized the importance of nonscientific studies. There are some undergraduates who follow more readily the guide of a professional faculty than the advice of college professors. In short, intelligent guidance would be possible. At present the competitive system and the mystery surrounding the science requirements put both the college teacher and the college student in a position where in many cases intelligent guidance is no more possible than in betting on a horse race. A further obvious advantage of the proposed scheme is that some 6,000 to 10,000 students who now prepare for medical school and fail each year to gain admittance would not be led down an educational path which comes to a dead end. Of course, even if this radical reform were widely adopted it would be necessary to reserve a certain number of places in each first year medical class for promising students who decided late in their college career to study medicine.

There are many objections to the proposal which I am sure are springing up in your minds. Most serious, at first sight, would be the difficulty of deciding at so early an age as to the promise or lack of promise of the boy in question. This difficulty is, I believe, not as great as might be assumed. The evidence available indicates that there is an excellent correlation between the criteria I have suggested and those usually employed (i. e. the total college record). If this is so, the mistakes would be no greater perhaps than now. The difficulties of judging as to the prospective student's character and personality are great, I admit. But, on balance, the advantages of such a scheme might outweigh the disadvantages.

Let me consider the question of the purely scholastic capacity of the student. At present this is estimated from the college record and from the letters that professors write about his actual ability in courses. The evidence which I have been able to gather indicates that there is a very close correlation, at least in Harvard College, between the work of the freshman year and the subsequent college record of the man. Furthermore, there is a fairly good correlation between many of the criteria which we use for admission such as school record and examination and the total college record. This being true, it is clear that there would be only a slight error introduced if the work of the freshman year and the school record were used as a basis for admission to the medical school instead of the present four years' work in college. To illustrate, may I give you a bit of evidence (I cannot claim it is conclusive) which I had gathered by the Assistant Dean of Harvard College. He examined the records of a group of men in Harvard College who went on to the Harvard Medical School and found the correlation coefficient between the freshman year's work and the whole college record to be 0.73 (significantly high). Or, to put the matter in more concrete form, let us suppose that the Harvard Medical School had selected from among the Harvard College candidates solely on the basis of their academic record. Of the first fifty-six men whom they would

take on the basis of their entire college record, forty-two would have been taken on the basis of the freshmen year alone. And, of the fourteen who would have been selected as freshmen but on the basis of their four year records would not have "made the grade," eight were borderline cases; and only six did very poor work during the remainder of their college career. There would have been six bad selections, but there is no reason at all why in such a scheme as I am suggesting acceptance might not be conditional on the student continuing to have a respectable record in the remaining three years of his college course. I think this evidence is enough to show that there is no very serious obstacle to the scheme from the point of view of estimating the student's intellectual capacity.

Now I, for one, am not ready to advocate this radical departure on a large scale. But I should like to urge that a conference of deans of half a dozen medical schools and a couple of dozen liberal arts colleges might explore the possibilities in this direction. What the proposal amounts to is a recognition that the four years in college and the four years in medical school be considered as a total educational unit and that the individual student be guided through these eight years by advice from both the college and the medical school authorities working together.

If such a conference of college and medical school authorities could be convened for a discussion of this problem, there are one or two other less radical suggestions I should like to urge for consideration. First, I should like a subcommittee of biochemists from the medical faculty and chemists from the college to try to formulate some more concrete outline of the minimum requirements. Similarly, the anatomists and the physiologists on the one hand and the biologists on the other might come together. I am not afraid of too narrow a premedical course nor am I afraid that the medical schools would dictate to the colleges. I believe cooperation is much to be preferred to the present highly unsatisfactory exchange of mutual recriminations.

Finally, I should like to urge upon the medical school faculties a serious consideration of ways and means of insuring that the future doctor may not only really receive the rudiments of a liberal education in college but be inspired to continue his liberal education throughout his professional course. To make any such proposal effective is difficult in the extreme. It can be done only if the medical school professors are willing to pay more than lip service to the ideals of a liberal education. Even four years in college devoted entirely to languages, literature, history, philosophy and the social sciences is too short a time to provide a truly liberal education. It is essential, it seems to me, to develop a sympathetic point of view in the medical schools toward a continuation of a student's education in something besides medicine. If the colleges will cooperate with the medical schools in guiding the student through the four years before he enters the medical school, will the medical schools in turn try to pay some attention to keeping alive the liberal arts tradition in the student's mind while he is studying medicine? Perhaps the history of medicine would provide in some instances the central core around which a continuation of liberal studies could be continued in a medical school. For others a discussion of the problems of socialization of medicine might furnish a basis for interest in something outside of medical work. Above all, if doctors could be made to acquire the habit of reading something other than scientific or professional literature on the one hand, or trash on the other, much of the complaint about the narrowly trained specialist would disappear. For the capable student who can work quickly there is time enough I feel sure. But the motivating force toward a liberal education is totally lacking in most of our professional schools today.

In short, I am advocating this morning a consideration by medical school and college authorities, acting together, of the scientific, professional and liberal education of the future doctor. I am suggesting that we try discarding the old concept of four years of scientific and liberal education followed by four years of professional training. In place of this we might regard the whole eight years as a unit with the aim of providing a balanced intellectual diet suited to each student's talents and interests in the hope that we might thus reach our goal of turning out both a well trained doctor and an educated man.

THE ORGANIZATION AND SUBJECT MATTER OF GENERAL EDUCATION

ROBERT M. HUTCHINS, LL.D.
President, University of Chicago
CHICAGO

Since you have two other college presidents on the program to tell you about college education it is obvious that you do not expect from any one of them the answer to your questions about it. You believe, like the rest of the world, that all presidents are liars, and you hope from a study of the differing lies of the three of us to discover the truth for yourselves. Speaking for myself, I find Mr. Conant's lies very persuasive, so much so that I shall drop out of this paper as I go along any lies of my own that are in conflict with his.

I assume that we are all agreed on the purpose of general education and that we want to confine our discussion to its organization and subject matter. I believe that general education should be given as soon as possible, that is, as soon as the student has the tools and the maturity it requires. I think that the program I favor can be experienced with profit by juniors in high school. I therefore propose beginning general education at about the beginning of the junior year in high school. Since I abhor the credit system and wish to mark intellectual progress by examinations taken when the student is ready to take them, I shall have no difficulty in admitting younger students to the program if they are ready for it and excluding juniors if they are not.

The course of study that I shall propose is rigorous and prolonged. I think, however, that the ordinary student can complete it in four years. By the ingenious device I have already suggested I shall be able to graduate some students earlier and some later, depending on the ability and industry that they display.

General education should, then, absorb the attention of students between the ages of 15 or 16 and 19 or 20. This is the case in every country of the world but ours. It is the case in some eight or nine places in the United States. Where the high school and the junior college are part of a large city school system, the organization

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 13, 1939.

has been successful. Where, as at the University of Chicago and Stephens College, the institution has either a small high school or none at all, the insignificant size of the first two years of the program and the large size of the last two create great difficulties. If you have seventy students entering the four year unit at the junior year in high school and 700 entering at the freshman year in college, it is absurd to talk about a coherent four year program. You must have a curriculum that the 700 can enter in the middle without being handicapped because they did not enter at the beginning.

If in such institutions as my own the scheme I advocate is to succeed, we shall have to convince local parents, at least, that it is wise for them to send their children to us two years earlier than they have been accustomed to sending them. I think that if parents cannot be persuaded to do this the University of Chicago should abandon collegiate work altogether and give up its freshman and sophomore years. Those years at present are a foreign body in the otherwise admirable constitution of the university. The students in them have different ambitions from those in the divisions above; the teachers have different ambitions, too. But if ties cannot be found for these two years above they must be found below; for I do not believe that two years at any level is long enough to provide an adequate education. It is suggestive that two year units do not exist anywhere else in the world; they are known only in the United States.

I may mention at this point one aspect of the organization of general education which ought to be trivial but in this country is most important. I favor awarding the bachelor's degree in recognition of general education; I favor awarding it at about the end of the sophomore year. This suggestion is not so startling as many people seem to think. President Butler of Columbia advocated it in his annual report for the year 1901-1902. In France the *baccalaureat* is used to indicate the satisfactory completion of general education. The reasons for giving it the same significance here are first that it now has no significance at all. The bachelor's degree means four years in college. As the president of Hiram has lately said, "To most college 'students' who sit long enough and patiently enough and docilely give back a modicum of the wisdom that has flowed past their ears, there will come in time the reward of their long-sitting, sheepskins to cover their intellectual nakedness. . . . The usual requirements for graduation, 'a minimum of 120 hours with additional credit for physical education,' may represent little more than hours of painful but patient sitting. Their blood relationship to achievement is so far removed as to make the claimed relationship laughable."

But it is not only the credit system and the examination-by-the-teacher-who-taught-the-course system that make the B.A. certify merely to four years of sitting. It is also and I think principally the fact that the standard four year college of liberal arts is and must be concerned with both general and specialized education. Even in some of the oldest and most conservative of these colleges you will find that the student may indulge in extreme specialization at an early stage. Yet the preparation with which students enter these colleges is such that the colleges must also give them a general education. These two aims can only confuse the colleges and hence confuse the significance of the degree that they offer.

Columbia, Johns Hopkins, Chicago and several other places have attempted to meet this situation by dividing the first two years from the last two. Some institutions have even given them different staffs and administrations. Here we face again the problems raised by two year units. The first two years is not long enough for general education; the last two is not long enough for advanced study. The remedy would seem to be a four year unit beginning with the junior year in high school and leading to the bachelor's degree, and after that a three year unit beginning with the junior year in college and leading to the master's degree. The bachelor's degree would then indicate an adequate general education and the master's an adequate experience in advanced study. This master's degree should also indicate that the holder is qualified for a teaching position in which research is not expected or required.

The last two years of the present college of liberal arts is left stranded when the college is divided into upper and lower divisions. We have found at Chicago that one of our more difficult problems is how to provide any intelligible plan of advanced study in the junior and senior year. Some of our departments have succeeded in persuading students to plan their courses beginning with the junior year for three years to the master's degree. These departments have been able to effect notable improvements in both the general cultivation and the specific training of their graduates. I recommend the award of the bachelor's degree at the end of the period of general education, that is at about the end of the sophomore year, for the sake of advanced study as much as for the sake of general education

It may be objected that many students will not want to add a year to their program of advanced study. This in my view is an argument for the plan. The educational system will be compelled to accommodate the youth of the nation up to the end of the junior college, that is, to about 19 or 20. There is no reason why it should accommodate them after that. Beginning with the junior year, education should be limited to those who are able and willing to profit by it. We should rigorously select our students at the university level, by which I mean the beginning of the junior year. Since, therefore, many students should terminate their education at the end of the sophomore year, one problem is how to induce them to do so. I think they will stay on and, through sheer importunity, get themselves a degree unless they can receive some recognizable and popular insignia at the end of the sophomore year. The bachelor's degree is recognizable and popular. Since it serves no useful purpose at present, I believe it should be made to serve the very useful one of persuading students to get out of education who should not be permitted to remain in it.

If general education is to be given between the beginning of the junior year in high school and the end of the sophomore year in college and if the bachelor's degree is to signify the completion of it, the next question is what is the subject matter that we should expect the student to master in this period to qualify for this degree?

Now I do not hold that general education should be limited to the classics of Greece and Rome. I do not believe that it is possible or desirable to insist that all students who should have a general education must study Greek and Latin. I do hold that tradition is important in education; that the primary purpose of education, indeed, is to help the student understand the

intellectual tradition in which he lives. I do not see how he can reach this understanding unless he understands the great books of the western world, beginning with Homer and coming down to our own day. If anybody can suggest a better method of accomplishing the purpose, I shall gladly embrace him and it.

Nor do I hold that the spirit, the philosophy, the technology or the theology of the Middle Ages is important in general education. I have no desire to return to this period any more than I wish to revert to antiquity. Some books written in the Middle Ages seem to me of some consequence to mankind. Most Ph.D.'s have never heard of them. I should like to have all students read some of them. Moreover, medieval scholars did have one insight; they saw that in order to read books you had to know how to do it. They developed the technics of grammar, rhetoric and logic as methods of reading, understanding and talking about things intelligently and intelligibly. I think it cannot be denied that our students in the highest reaches of the university are wofully deficient in all these abilities today. They cannot read, write, speak or think. I do not suggest that we should attempt to introduce the trivium and quadrivium into the American college. I do say that we must try to do for our own students what the seven liberal arts did for the medieval youth. If the Middle Ages have any suggestions to make on this point, we should welcome them. We need all the help we can get.

I should like to remark in passing that in the Middle Ages people went to universities at 13 or 14. They read books and experienced disciplines that are regarded as far too difficult for university professors today. Most of the great books of the western world were written for laymen. Many of them were written for very young laymen. Nothing reveals so clearly the indolence and inertia into which we have fallen as the steady decline in the number of these books read in our schools and colleges and the steady elimination of instruction in the disciplines through which they may be understood. And all this has gone on in the sacred name of liberalizing the curriculum.

The curriculum I favor is not too difficult even for very ordinary American students. It is difficult for the professors but not for the students. And the younger the students are the better they like the books, because they are not old enough to know that the books are too hard for them to read. Something like the course of study I should favor is now in force at St. John's College, Maryland. There an unselected group of indifferently prepared students are studying these books with tremendous enthusiasm thirty-five hours a week. They read last fall ten dialogues of Plato and voted to have extra classes so that they might read and discuss the rest of them. In connection with the reading, they are going through a formidable course of instruction in grammar, rhetoric, logic and mathematics.

The entire freshman class at Columbia is now reading and discussing twenty-five of the great books in philosophy and literature. I understand that Rushing Week at Columbia was a failure because the students were too interested in the reading to be interested in fraternities, that the books are the chief subject of discussion at all informal student gatherings, and that the only complaint comes from teachers in other courses who feel that their work is suffering from the excitement the books in the Humanities course arouse. For eight years and more I have taught these books to unselected pupils in our University High School and to freshmen, sophomores, juniors and seniors in college. Not one of them has suggested that the books were too hard or that they were not worth reading. I can testify from this experience, though not, of course, very scientifically, that students who can read anything thrive on these books and that the younger they are the more they thrive.

Those who think that this is a barren, arid program, remote from real life and devoid of contemporary interest have either never read the books or do not know how to teach. Or perhaps they have merely forgotten their youth. These books contain what the race regards as the permanent, abiding contributions its intellect and imagination have made. They deal with fundamental questions. It is a mistake to suppose that young people are interested only in football, the dramatic association and the student newspaper. I think it could be proved that these activities have grown to their present overwhelming importance in proportion as the curriculum has been denatured. Students resort to the extracurriculum because the curriculum is stupid. Young people are interested in fundamental questions. They are interested in great minds and great works of art. They are, of course, interested in the bearing of these works on the problems of the world today. It is, therefore, impossible to keep out of the discussion, even if the teacher were so fossilized as to want to, the consideration of current events. But these events then take on meaning; the points of difference and the points of similarity between then and now can be presented. Think what a mine of references to what is now going on in the world is Plato's Republic or Mill's Essay on Liberty. If I had to prescribe an exclusive diet for young Americans, I should rather have them read books like these than gain their political, economic and social orientation by listening to the best radio commentators or absorbing the New York *Times*. Fortunately we do not have to make the choice; they can read the books and listen to the commentators and absorb the New York *Times* too. I repeat: these important agencies of instruction—the radio and the newspaper—and all other experiences of life, as a matter of fact—take on intelligibility as the student comes to understand the tradition in which he lives. Though we have made great advances in technology, so that the steam turbine of last year may not be of much value in understanding the steam turbine of 1939, we must remember that the fundamental questions today are those with which the Greeks were concerned; and the reason is that human nature has not changed. The answers that the Greeks gave are still the answers with which we must begin if we hope to give the right answer today. The answers they gave have affected human history so profoundly that we cannot approach the issue of the purpose of the state, for example, without unconsciously reflecting their views. We may apply to these early thinkers the words of Cardinal Newman about Aristotle: "Do not suppose, that in thus appealing to the ancients, I am throwing back the world two thousand years, and fettering philosophy with the reasonings of paganism. While the world lasts, will Aristotle's doctrine on these matters last, for he is the oracle of nature and of truth. While we are men, we cannot help, to a great extent, being Aristotelians, for the great Master does but analyze the thoughts, feelings, views, and opinions of human kind. He has told us the meaning of our own words and ideas, before we were born. In many subject-matters,

to think correctly, is to think like Aristotle; and we are his disciples whether we will or no, though we may not know it." Do not suppose that in thus including the ancients in my course of study I am excluding the moderns. I do not need to make a case for the moderns. I do apparently need to remind you that the works of the ancients lie at the foundation of the tradition in which we live.

Do not suppose, either, that because I have used as examples the great books in literature, philosophy and the social sciences I am ignoring natural science. The great works in natural science and the great experiments must be a part and an important part of general education. Here again I am not concerned with the method; I am concerned with the end. The student should understand the leading ideas in the natural sciences. Do you think he does today? On the contrary, what he gets today is either a superficial shower from a survey course or professional instruction from the first day of the freshman year, based apparently on the notion that every member of the class is going to be a chemical engineer. General education is not professional education. The curriculum must be designed to prepare the student for intelligent citizenship. The type of scientific instruction that I received in college has no place in the kind of college I am proposing. As for survey courses of the usual variety, they have no place there either. They degenerate too easily into a rapid tour of all the facts known in physics, chemistry and biology. The basis of the scientific program should be the great landmarks of scientific work, the books and the experiments.

Neither at Columbia nor at Chicago has anybody interested in the kind of curriculum I am suggesting had the facilities for the kind of scientific instruction we have wanted to give. At St. John's College those facilities are available and are now being used. It appears that between a half and a third of the course of study will be mathematics and natural science. In fact, St. John's is the only college in the country in which every student must take laboratory science for four years.

Another problem that has disturbed those who have discussed this issue is what books I am going to select to cram down the throats of the young. The answer is that if any reasonably intelligent person will conscientiously try to list the hundred most important books that have ever been written I will accept his list. I feel safe in doing this because (*a*) the books would all be worth reading and (*b*) his list would be almost the same as mine. There is, in fact, startling unanimity about what the good books are. The real question is whether they have any place in education. The suggestion that nobody knows what books to select is put forward as an alibi by those who have never read any that would be on anybody's list.

Only one criticism of this program has been made which has seemed to me on the level. That is that students who cannot learn through books will not be able to learn through the course of study that I propose. This, of course, is true. It is what might be called a self-evident proposition. I suggest, however, that we employ this curriculum for students who can be taught to read and that we continue our efforts to discover methods of teaching the rest of the youthful population how to do it. The undisputed fact that some students cannot read any books should not prevent us from giving those who can read *some* the chance to read the best there are.

I could go on here indefinitely discussing the details of this program and the details of the attacks that have been made on it. But these would be details. The real question is Which side are you on? If you believe that the aim of general education is to teach students to make money; if you believe that the educational system should mirror the chaos of the world; if you think that we have nothing to learn from the past; if you think that the way to prepare students for life is to put them through little fake experiences inside or outside the classroom; if you think that education is information; if you believe that the whims of children should determine what they should study, then I am afraid we can never agree. If, however, you believe that education should train students to think so that they may act intelligently when they face new situations; if you regard it as important for them to understand the tradition in which they live; if you feel that the present educational program leaves something to be desired because of its "progressivism," utilitarianism and diffusion; if you want to open up to the youth of America the treasures of the thought, imagination, and accomplishment of the past, then we can agree, for I shall gladly accept any course of study that will take us even a little way along this road.

REFRESHER COURSES IN CLINICAL PEDIATRICS

AN EXPERIENCE IN POSTGRADUATE EDUCATION

AMOS CHRISTIE, M.D.
SAN FRANCISCO

Two fundamental pedagogic methods have guided all attempts at postgraduate medical education. Information developed at medical centers must be taken to the practitioner or the practitioner must be brought to the medical center for organized teaching in the medical specialties. For various reasons both methods have met with only moderate and in many cases no success. The reasons for this are (1) the expense of organization of postgraduate medical courses at the medical centers for the few physicians who are able to get away from their practice, (2) the expense to the physician student of remaining away from his practice for from four to six weeks and (3) in the bringing of medical school teachers to the practicing physician, the lack of understanding by the academician of the problems which confront the general practitioner. Because these methods of instruction are markedly different from those used for undergraduate medical students, many mistakes have been made in choosing teaching personnel. In other words, there has been a lack of experienced teaching personnel in this field. Finally, there has been lethargy on the part of the medical profession in recognizing the needs and benefits (value) of adequate postgraduate medical education.

With the passage of the Social Security Act in 1935, adequate funds became available for the first time to supply postgraduate teaching to the physicians of the United States. At the end of the fiscal year 1936-1937 (June 30, 1937) postgraduate training was provided with child and maternal health funds for local practicing physicians and dentists in thirty-four states. Of these states twenty-two reported a total enrolment of

From the Utah State Board of Health and the Curricula of Public Heath and Department of Pediatrics of the University of California Medical School.

6,193 physicians in obstetrics and nineteen an enrolment of 5,009 physicians for courses in obstetrics.

It is now time to analyze the methodology in this teaching and to attempt to benefit by the experience of those who have been engaged in the work. It is my purpose in this paper to describe an experience in public health teaching which was conceived and carried out as an experiment in postgraduate education. The results are still somewhat intangible, but it is hoped that in a follow-up report some member or members of the Utah State Board of Health will write a critical analysis from their point of view. This may indicate what plan of approach was best in order that such a course may be more successfully repeated.

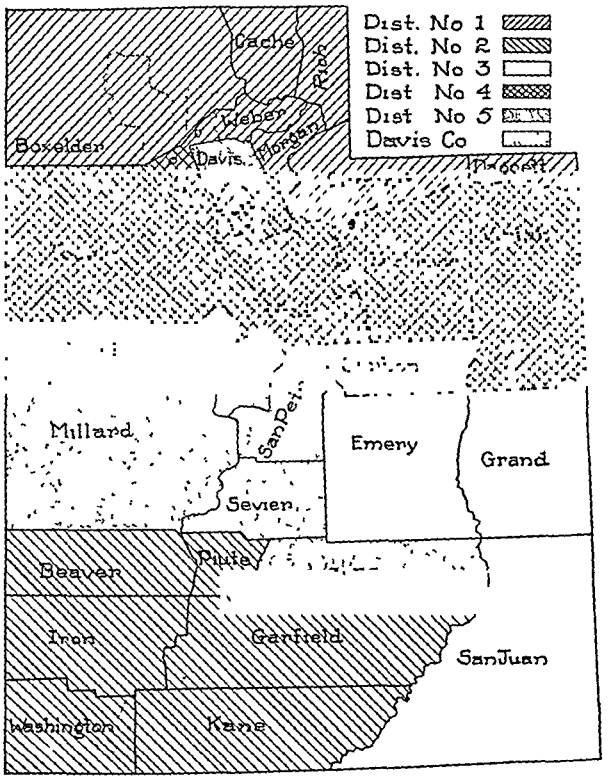
ORGANIZATION OF THE UTAH STATE BOARD OF HEALTH TO ADMINISTER MATERNAL AND CHILD HEALTH SERVICES

The state of Utah is essentially rural. The total population in 1930 was 507,847.[1] Of the twenty-nine counties all but five have a population density under ten persons per square mile.

There are 508 physicians in the state, with the number of persons per physician ranging from 719 in Salt Lake County to 2,703 in Tooele County. Under the state board of health the local health regulations are administered under the district plan. The state is divided into five health districts and one full time county health unit. Each district is administered by a full time health officer holding a certificate in public health.

The division of maternal and child health is administered from the state office by a director. A supervising nurse in this division administers the public health nursing program, working with the supervisors in each district and the public health nurses under a generalized nursing plan.

A nutritionist and an adviser on school health education are employed under the division of maternal and child health. Briefly the program of this division is to give advisory and consultation service to all local health groups and agencies, particularly in rural sections and sections of greatest economic need; to employ local physicians to conduct well baby, preschool and health conferences; to promote immunization against the communicable diseases; to promote better nutrition and health education in the schools, and to correlate these integral parts of the program with the dental and the crippled children's program wherever this is possible.



The well baby and preschool conference and immunization program are conducted under the supervision of the district health officers and the director of the maternal and child health division of the Utah State Board of Health by qualified local physicians, certified by the component society and approved by the state board of health. The state board of health pays local physicians at the rate of $5 for the first hour and $2.50 for each subsequent hour, with a travel allowance of 10 cents a mile beyond 5 miles. About $19,000 was budgeted for this during the current fiscal year.

With this administratively sound program it soon became apparent that in many cases the local physicians were deficient in modern technics on the conduct of well baby conferences and factual information demanded by many parents. Consequently it was deemed advisable to conduct postgraduate courses in order to raise the general standard of these conferences, and in May 1938 I accepted an invitation from the Utah Board of Health to spend two months in that state with this purpose in mind. The following program was developed with the sanction of the state medical society.

1. Houston, D. C., and Hill, R. M. Heath Conditions and Facilities in Utah, Utah State Planning Board, April 1936.

METHODS USED IN POSTGRADUATE TEACHING

In each case the details of the program were left entirely in the hands of the district health officer, and he used the services of the consultant as he felt would best suit the component medical societies. These societies were advised that the time allotted to each district would be on the basis of the number of physicians in the district. Consequently two weeks was spent in each of districts 1, 4 and 5, with one week each allotted to districts 2 and 3. The wisdom of this division of time will be discussed later.

Public health districts of Utah in 1938

There are three groups which the consulting physician meets in conducting postgraduate medical courses. The approach is quite different with each.

The Public.—This group is starved for accurate information concerning the scientific facts of maternal and child care. This is not so much the fault of the local physician as it is the result of fads and misinformation given to the public by their grandmothers and by lay magazines. Consequently education must be given; for example the details of adequate antepartum care and data as to the value of and time for immunization are frequently requested by parents. A common sense talk on child training and guidance is also in order. These are usually given at public meetings, and herein lies their greatest shortcoming. The information does not reach a sufficient number of people to make it worth while. The more intelligent people of the community are always present, but those who need it most are invariably absent. Several public meetings of this type were held in all but one district. They were attended by from fifty to 250 mothers, grandmothers and teachers and a few fathers. The talks given became standardized

to include an introduction aimed at showing the need for cooperation with the district health officer and the scope of the general public health movement. This gave an opportunity to include in a subtle way such information as the need for antepartum Wassermann tests and venereal disease control in general. Infant feeding, including solid food additions and the need of and time for immunizations were discussed, and recent advances in these fields were outlined. Finally, about fifteen minutes was devoted to habit formation and child guidance work. This part of the talk invariably precipitated a number of interesting questions for further discussion. It was my feeling that this method was a very strenuous one for the consultant to repeat in each town, considering the relatively few people reached.

TABLE 1.—*Sample Schedule for Dr. Amos Christie, Assistant Professor of Pediatrics, University of California Medical School, in Health District No. 4*

		July 11-July 23, 1938	
Date	Time	Place	Service
July 11	a. m.	Santaquin	Consultation with physicians
	p. m.	Vernal	
July 12	a. m.	Maeser	Infant and preschool conference
	p. m.	Vernal	Consultation with physicians
July 13	a. m.	Mount Emmons	Infant and preschool conference
	p. m.	Roosevelt Fort Duchesne	Consultation with physicians
July 14	a. m.	Upalco	Infant and preschool conference
	p. m.	Whiterocks	Consultation with physicians Return to Provo
July 15	a. m.	Provo	Consultant, crippled children's diagnostic clinic
July 15	p. m.	Provo	Consultant crippled children's diagnostic clinic
July 16	a. m.	Provo	Office administration
	p. m.	Provo	Office administration
July 18	a. m.	Provo	Consultation with physicians
	p. m.	Provo	Consultation with physicians Meeting of Utah County Medical Society and registered nurses
July 19	a. m.	Provo	Consultation with physicians
	p. m.	Pleasant Grove American Fork	Consultation with physicians
July 20	a. m.	Provo	Office
	p. m.	Provo	Consultation with physicians
	Evening		Pediatric clinic with Utah County Medical Society
July 21	a. m.	Provo	Consultation with physicians
	p. m.	Lehi and American Fork	Consultation with physicians
	Evening		Public meeting sponsored by Utah County Medical Auxiliary
July 22	a. m.	Provo	Office
	p. m.	Provo	District nurses' conference
July 23	a. m.	Provo	District nurses' conference

The radio should offer, whenever available, a means of getting the required information to more people. Its shortcomings, however, are obvious to all who listen to it. For programs to be effective the script must be professionally prepared, and such service is usually not obtainable.

This medium, however, was tried in a district where a small radio station had an outlet of a possible 27,000 listeners. A time (from 5 to 5:30 p. m.) was arranged, and two half hour broadcasts were given. The subjects were "Diet and Growth in the Young Infant" and "The Premature Infant." The scripts were prepared with the idea of the listener's interest, and after each ten or twelve minutes a woman's voice was interjected to ask specific leading questions. In this way detailed information as to additions of solid food and the need and reason for cod liver oil, for example, were covered. The same voice, impersonating a typical mother, also asked pointed questions and was answered in conversational style concerning the prophylaxis of communicable diseases.

This method would seem more logical than the public meeting for reaching the public and would allow the physician more time for contact with the local physicians.

The Physician.—Three methods were used in reaching the medical profession: (1) the personal visit to the physician's office, (2) meetings of the component medical societies, at which clinics were held and talks given, and (3) attendance, on invitation, by from two to four physicians at a properly conducted well baby conference. The third method was most difficult, yet successful.

It is problematic which of the three methods can be used to the greatest advantage and which should precede the other. If a satisfactory meeting with good attendance can be arranged with the county medical society, this offers the greatest possibility of results because all further teaching methods to be used are dependent on the initial contact. The consultant must give a tactful and sincere presentation of what he is attempting to accomplish. It must be followed by a talk (not a lecture) on one of several subjects of practical value to the practitioner. I myself have discussed such subjects as recent advances in sulfanilamide therapy and some aspects of congenital syphilis. These subjects were of topical interest at the time and of definite value to the practitioner. The latter subject also allows for the opening of a discussion of adequate antepartum care.

In one county such a didactic talk was followed by a clinic. This included the presentation in academic style of from five to seven cases which were of diagnostic, prognostic and therapeutic interest. With overemphasis on suggestions of practical value, the way is open for pleasant and adequate contact with physicians in their own offices.

Office visiting is generally unsuccessful unless the practitioner has spent some time and thought preparing for the interview. Frequently he does not realize his problems or is reluctant to reveal his apparent inadequacy in a discussion of recent advances. The most subtle methods must frequently be used to draw him out. This was accomplished in some cases by an informed third person asking leading questions.

These personal interviews are of great value to physicians, and, if the physicians can be encouraged to ask their problem patients to come to the office for consultation, much teaching can be accomplished in an hour and a half or two hours. The consultant should be prepared to visit the homes of the patients, and a diagnostic bag is a minimum requirement.

There is a small group of older physicians who desire to show their complete ability to handle all problems pertaining to the diseases of men, women and children and who do most of the talking. No method was found to combat this type of individualism, and I am convinced that only a successful contact or repeated visits in a meeting of such a physician's colleagues will engender the necessary feeling of cooperation for a successful follow-up. It cannot be too firmly emphasized that in all relations with fellow practitioners the entire tone of the meeting or personal interview should be so conversational as to break down any prejudice against the visiting professor, whose ideas might be too unpractical and academic to be of use to the practitioner. Material must be presented with the attitude of "here it is if you can use it."

It should be remembered that the primary purpose in Utah was to raise the standards of well baby conference work, for which state and federal funds were being spent liberally.

Most practicing physicians who have been out of medical school more than ten years do not realize the tremendous educational value to the mother of this type of conference and have not kept up with the demands on the part of parents to know the fundamentals of habit training or the striking clinical points, such as rickets and anemia, which the physician should observe in such an examination. The conduct of the well baby examination is unique, and yet it is only with considerable difficulty and tact that it is possible to make the older physician receptive to this type of demonstration. Care should be taken in such teaching not to have too many cases. From eight to ten are sufficient for a two and a half hour clinic, and when they are carefully chosen by the public health nurses much can be accomplished. The importance of history taking, the value of reemphasis to the mothers and the fundamentals of infant feeding and solid food additions may be brought out. The value of prophylaxis against communicable diseases must be emphasized, and mothers should be encouraged to discuss their children's habit problems.

It is my feeling that herein lies the major value of the well baby conference and that an excellent bit of teaching can be given by efficient demonstration. The smile of satisfaction on the part of the mother whose questions have been adequately answered and whose baby has been completely examined will be sufficient evidence that the well baby conference to be successful must be more than a baby show or a weighing by the nurses. It must be conducted by a physician qualified to interpret disease at its outset and capable of making an examination sufficiently complete to promote confidence. He must be able to handle questions the answers to which are in any government bulletin on infant care or child management and are not the magic of pediatricians only.

The Public Health Personnel.—Factual information given to the health officers and public health nurses can be of considerable value to them in their future contacts with the medical profession. Therefore an association of the consultant with the public health officer is of importance in refresher courses on recent advances in maternal and child health, bringing communicable disease control and immunization methods up to date. There is no place in rural health work for the "arm chair health officer." The best health officer is first a good doctor and then a health administrator and educator. In other words, the health officer who will roll up his sleeves and use his training and knowledge of practical clinical problems to assist the practitioner will promote his program further and faster than the desk sitting type of health administrator. The schools for the training of rural health officers will do well to recognize this fact.

The district health officer and the public health nurse are the keystone of any program, and any association by them with the consultant is desirable. The health officer is the one to introduce the consultant to the physicians, as such an introduction should improve his future contact with them.

In each health district a nursing conference was called on the last day on which the consultant would be in that district. Discussions of local problems pertaining to the program were carried out openly and frankly, and considerable good work was done. At many of these joint meetings of public health personnel, social workers were invited and principals of schools attended. This presented an excellent opportunity for actual case studies to be shown. It was possible to demonstrate where better correlation of existing facilities would lead to greater efficiency in the broad program.

Two sample schedules made out by district health officers are shown in the accompanying tables. These were arranged through the cooperation of the secretaries of the medical societies and were circulated to all physicians. In this way any physician could participate in all or parts of the program.

THE EDUCATION OF THE CONSULTANT

It has been suggested that many mistakes have been made in postgraduate medical education by a teaching personnel untrained in the technics of teaching persons whose very choice of the medical profession spells "rugged individualism." It would therefore be unfair to omit in such an analysis as this a discussion of the ways in which my eyes were opened to the needs and local conditions confronting practitioners and rural health officers. It was possible to observe rural health

TABLE 2.—*Sample Schedule for Dr. Amos Christie, Assistant Professor of Pediatrics, University of California Medical School, in Health District No. 5*

Date	Town	Service
July 26	Nephi	Consultations with physicians
July 26	Mount Pleasant	Public address, 8 p. m.
July 27	Fairview	Consultations with physicians
July 27	Ephraim	Consultations with physicians
July 27	Manti	Consultations with physicians
July 28	Spring City	Infant conference, 9:30 a. m., relief society room
July 28	Mount Pleasant	Medical meeting, 8 p. m., Dr. Madsen's office
July 29	Gunnison	Infant conference, 10 a. m., town hall
July 29	Chester	Infant conference, 2 p. m., schoolhouse
July 29	Manti	Medical meeting, 8 p. m., schoolhouse
July 30	Salina	Consultations with physicians
August 1	Annabella	Infant conference, 10 a. m., relief society room
August 1	Venice	Infant conference, 2 p. m., church house
August 1	Richfield	Medical meeting, 8 p. m., Dr. Lowe's office
August 2	Bicknell	Infant conference, 10 a. m.
August 2	Soa	Infant conference, 2 p. m.
August 3	Scipio	Infant conference, 10 a. m.
August 3	Fillmore	Public address, 3 p. m., first ward church
August 4	Oak City	Infant conference, 10 a. m., church house
August 4	Hinckley	Infant conference, 2:30 p. m., grade school
August 5	Eureka	Infant conference, 10 a. m., school
August 5	Manti	Talk to welfare group, 2 p. m., court house

administrative problems which had been discussed in the classroom under actual test in the field. This practical experience should enable one to temper and even change many of one's theoretical ideas in the future. An example is my conviction that well baby conferences in rural communities must be open to all socio-economic groups. I am certain that there is no place in rural health work for well baby conferences limited to indigents.

Much was learned from rural practitioners in the way of clinical pediatrics. A notable instance was the experience of seeing eight patients with Rocky Mountain spotted fever. Colored photographs of rashes were obtained which will be of inestimable value for medical school teaching, and observations were made on the value and limitations of the vaccine prepared for this condition.

There was an opportunity to study the cause and clinical picture of pseudohypertrophic muscular disease, which seemed to have a high incidence in the state.

Other unusual educational opportunities presented themselves. Observations were made on the mottled tooth enamel due to the high fluoride content of the water of certain isolated areas in Utah. The seeming geographic and climatic incidence of rheumatic fever, previously described by Paul, was also noted. The high

incidence of thyroid enlargement in school children and of rickets in certain communities and the sharply localized areas of tremendous tonsillar hypertrophy were a constant source of interest and education.

A cooperative medical plan started in an isolated county whose people were without the services of a doctor for four years was observed in operation and studied with interest.

SUMMARY

Throughout these experiences in the postgraduate teaching field, the several approaches noted were evaluated with the idea of setting up a better program if it was to be repeated under somewhat similar circumstances in another community. Certain opinions were gained which should be of value in the repetition of an organized program in postgraduate medical education.

The practitioner has developed a tremendous responsibility to his patients. He cannot afford to leave his community for refresher courses for as long as two weeks. The people have learned to depend on him to a point where they will not accept a temporary locum tenens for even that short period. The practitioner feels this responsibility keenly and, despite any possible changes in the practice of medicine which may result from the changing times, this patient-doctor relationship must be preserved. It is for this reason that postgraduate medical education must be taken to the doctors.

I would suggest that this may best be done by a full time physician, whom I choose to call a circuit rider. This term has the connotation of the lawyer who pioneered the West, as did Abraham Lincoln in his day. A full time person, well trained in a branch of clinical medicine and serving for not longer than two years, could learn much to take back to his medical center and by reason of his academic training could keep the practitioners in the outlying districts well up on his subject. By traveling from place to place, by knowing local conditions and by possessing factual information and tact, he might be able to raise the standards of medical practice to a high degree. Herein may lie the future of postgraduate medical education.

There should be a well defined purpose before such a program is initiated, and this should be kept in mind at all times. If this purpose is to raise the standard of well baby conferences, all efforts should be directed to this purpose, at the sacrifice of lay education, nursing education or the solving of individual medical problems of the physicians.

The greatest need for postgraduate medical education or refresher courses in pediatrics is felt by men who have been away from medical school more than five years. More time must be allowed for those rural areas where it is impossible for the physicians to leave their practices for refresher courses.

This brings up the question of division of time, and a better arrangement should be sought than time per number of physicians in any one area. I would suggest that a short course of lectures does not reach the physicians who need the instruction most. Two weeks is insufficient for the accomplishment of anything constructive in any one area or district. One month or, preferably, two months should be the minimum requirement. I believe that the consultant should acquaint himself first with local conditions and the personalities peculiar to the area. In this way he can accomplish more, particularly if the available time is not spread too thinly over too wide an area.

Choosing the person who is to act as consultant or instructor is most important, and time, thought and energy should be expended on obtaining the best possible physician. In other words, for a well defined purpose a clinical instructor may be a better selection than a professor. Graying hair will stand in good stead for the consultant.

It is a well known fact that one of the great deficiencies in the training of health officers has been the lack of adequately trained teaching personnel with an understanding of postgraduate educational technics to give these men the real benefit of the progress in public health. It would be well to spend some of the available funds in the teaching of teaching personnel. I believe that the training of health officers for rural areas should be directed more along clinical lines. The promotion of a program is best accomplished by a health officer who, by reason of his knowledge of clinical medicine, can be of positive assistance to the practitioner in his clinical problems.

It would seem that the extension of education to the people has given rise to the national health movement. There is no evidence of an ebbing tide. It is my hope that this record of an experience in postgraduate education will stimulate further reports so that inadequacies may be realized and technics sought for remedying them.

THE COMMUNITY HOSPITAL

WHAT IT SHOULD BE

BARRY C. SMITH
General Director, the Commonwealth Fund
NEW YORK

In considering this subject—particularly at the present time when the question of great expansion of hospital facilities at governmental expense is under discussion—the matter of definitions appears of outstanding importance. Just what is meant by the term "hospital" and just what is a "community hospital"?

Is a hospital simply a building where the sick may be housed and presumably cared for by one or more members of the medical profession or is it, to be worthy of the name, far more than that?

In THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of June 11, 1938, it was stated that in the entire United States there are "but thirteen counties no part of which is within thirty miles of a registered general hospital."[1] This statement presumably was intended as anticipatory evidence that the need for additional hospital facilities, as later set forth by the Technical Committee on Medical Care in Washington last July, was exaggerated, and the argument was buttressed at the very end by the statement "There may be some localities in which hospital facilities are needed. However, the Commonwealth Fund, which for the past ten years has been awarding hospitals to communities which seemed to be able to maintain such institutions with proper standards, has thus far made eleven awards." This statement is but a weak buttress for, while it is true that only eleven awards were made, the reasons were, first, financial limitations, each hospital, with nurses' home and equipment, costing the Commonwealth Fund on the average about $235,000; and, second, the fact that the staff of the Commonwealth

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 13, 1939.

1. Distribution of Hospital Service, *Current Comment*, J. A. M. A. 110: 2013 (June 11) 1938.

Fund's Division of Rural Hospitals, for a minimum period of five years and frequently for a longer time, has found it necessary to devote much time and attention to the establishment and maintenance of operating standards—matters with which the rural community is usually reasonably unfamiliar and which have some bearing on the importance of the definition of a hospital above referred to. Even the fact that a community "seemed to be able to maintain proper standards" is far from a guaranty that it will do so or even knows how. Certainly the fact that only eleven awards were made bears little relation to the need for additional rural hospitals or to the number of applications received, which have run into the hundreds.

Again, a "registered hospital," [2] says the American Medical Association, means one concerning which "evidence concerning irregular or unsafe practices . . . has not come to the attention of the Council on Medical Education and Hospitals." On this basis, 6,128 hospitals are on the latest registered list and 617 are omitted.[3] Members of the staff of the Commonwealth Fund have visited a good many registered hospitals which in our opinion are anything but assets to their communities and which in some cases are little if anything more than rather badly run boarding houses for the sick, with little and poor equipment and with questionable medical or surgical service. Many of these are very small; many are proprietary, sometimes operated by physicians of doubtful education and experience, in which some odd medical procedures are carried on.

Let me hasten to say that I am not indulging in that form of indoor sport, which is at present quite popular, of damning the American Medical Association. On the contrary, while it may perhaps be considered, with justice, somewhat overly conservative, it has among other valuable achievements done a great job in improving the standards of medical practice and of medical education, and in protecting the public. It has also done much of value in the hospital field, and since it can scarcely be expected to investigate on the ground every two-by-four establishment that chooses to call itself a hospital, perhaps we of the Commonwealth Fund staff and others familiar with hospitals are to blame for not calling "irregular and unsafe" practices to the attention of the Council on Medical Education and Hospitals; or, possibly a wiser policy would be to register only hospitals known to be regular and safe rather than those not known to be irregular and unsafe.

However, lest I still be misunderstood, let me turn momentarily to another side of the picture. Within the last few months an individual who is greatly interested in the hospitalization phase of the National Health Program proposed at the Washington Conference last July argued at some length, in conversation with me, for the establishment of very small (eight to twelve bed) hospitals—"crossroads hospitals," I believe this person called them—to be located in sparsely populated and very poor rural districts, to be "reasonably protected from fire" and equipped with a "moderate x-ray and simple laboratory." While in my judgment reasonable protection from fire is obtainable, when one is talking of hospitals, only by absolutely fireproof construction, and while I was not and am not particularly clear as to what a "moderate x-ray and simple laboratory" might be, nevertheless, admitting these points as possible for the sake of the argument, I inquired how in such a hospital, in such a community, it would be possible to supply the necessary medical and surgical service of really good quality, the technical service for the operation of the alleged x-ray and laboratory, satisfactory graduate nursing personnel, and the various other things which go to make up a hospital worthy of the name. To my complete astonishment the answer to this question was "All that is really needed is a good surgeon." Asked how such a good surgeon could be obtained in such a community where usually one is not likely to be found, the answer was that he could be imported. In my judgment, really good care for the patients in a hospital requires a number of other branches of medical service of high quality in addition to surgery. Nor does it seem to me likely in a community so sparsely settled and so poor in resources that no good surgeon has ever been attracted there, that one could be imported and persuaded to stay there even by a government subsidy, considering the opportunities for good surgeons in more pleasant regions. Again, the advocacy of such a plan for hospital expansion makes important the definition of a hospital.

A GOOD COMMUNITY HOSPITAL

If I may venture to say so, without being too obvious, it would seem to me that an adequate definition of a hospital which would render a worth while service to a given rural community involves two parts: the first relating to the building and its equipment, the second to the quality and type of service rendered within that building.

The building should be absolutely fireproof, whether large or small. It should be equipped not necessarily for every service which the best urban medical centers are prepared to render but certainly for every service which a reasonably competent medical profession is able to provide and without such equipment cannot provide satisfactorily. Such equipment should certainly include first-class clinical laboratory facilities, an x-ray plant adequate for diagnostic purposes, but not for therapy unless there is a physician trained to administer it, properly lighted, ventilated and equipped operating and delivery rooms, necessary facilities for the preparation of food including special diets, an adequate heating plant, reasonably comfortable wards and rooms—all these things to the extent that you are all familiar with—together with the best arrangements possible to emphasize what may be termed the safety factor, such as is provided by well separated operating and delivery rooms, isolation facilities for contagious cases, provision for prevention of cross infections, and so on. Certainly such conditions as have been recently related to me concerning a small "hospital" containing five patients in close proximity, three postpartum cases, one of scarlet fever and one of poliomyelitis do not make possible the type of provision indicated. One might add as a desirable if not essential quality such planning as will make for convenience in careful and orderly service, with absence of unnecessary noise and fatigue. The list could be enlarged.

Given such a plant, of what value will it be? That will depend entirely on the quality of those who are available to utilize the facilities and render the necessary service—the physicians and surgeons, the nurses, technical assistants for the x-ray and laboratory, even the cook.

Such a plant is largely useless without competent physicians, surgeons and other personnel. Nor can the best of physicians and surgeons serve their patients to good advantage without first-class facilities. Granted

2. Hospitals Registered by the American Medical Association, J. A. M. A. **110**: 986 (March 26) 1938.
3. Summary of Hospital Data, J. A. M. A. **110**: 959 (March 26) 1938.

that there are cases on record of difficult operations successfully performed on the kitchen table with the most primitive appliances, it is the successful ones, I suspect, that we hear about and not the failures—or the unnecessary deaths.

This, then, would be my definition of a hospital: a fireproof, properly equipped plant (whether small or large) with a medical staff and other personnel competent to render the service made possible by such a plant. With full realization that good hospitals vary somewhat in the degree of their excellence and that the competence of the physician is a relative matter, even so there is a minimum in terms of plant, equipment, medical staff and personnel below which a hospital ceases to be an asset and in my judgment becomes a liability—even a menace to the people of a community—and I fear that the descent below that minimum is far more common than is generally known.

If this definition is so far correct or even approximately so, it requires to be considered in determining the need for additional community hospitals and of how best to meet that need.

A community hospital is simply a general hospital which is prepared to serve the people of its community without regard to race, creed or financial status. It must be prepared to render a large amount of free service. Either a private voluntary hospital or a public, tax-supported one may render such service of high quality. Few proprietary hospitals render any great amount of free service or provide opportunities for hospital service to more than a small fraction of the physicians of the community; and few therefore can qualify as community hospitals. The Commonwealth Fund in its rural hospital program has devoted its attention to the type of hospital organized as a corporation not for profit, governed by an elected voluntary board and conducted by agreement in accordance with accepted standards. This is not to say that a public hospital cannot be operated as a community institution with equally high standards, provided—and this is not always easy—political control is avoided.

A community hospital of the type I have been attempting briefly to indicate should be of what size and serve how large an area? These two matters are somewhat interrelated. Such a hospital must make provision for patients of both sexes, of different races (certainly in the South), for different types of conditions which require to be separated. With the provision of such bed facilities and of the various types of equipment and of technical service, it has appeared from our experience that twenty-five beds is an irreducible minimum to provide what the various patients require and do it at reasonable expense. From forty to fifty beds has appeared a better minimum, permitting a wiser and more careful segregation of patients and a lower patient day cost. Nor does there appear any reason why such a hospital should not serve a population within a radius of 25 to 35 miles regardless of county lines. With the improvement of roads and transportation facilities that has, again in our experience, proved entirely practicable.

SPECIAL PROBLEMS

What then of the various sparsely settled and very poor areas—such for example as may be found in Catron County, New Mexico? This county, of some 7,000 square miles, had a population in 1930 of 3,283; in 1931 it had one physician. If such a hospital as I have described should be built there, how would it be staffed, how many occupants would it have? A circle of 35 miles radius in such a county would have a population of less than 400. Build a hospital as small as you like, run the cost of operation per patient as high as you like, still in such an area how can medical, nursing and other technical service of competent character be obtained and retained? I do not know the answer. Perhaps there is no satisfactory answer; perhaps it would be better for the patient to be taken long distances to a really good institution rather than to risk the poor quality of care which is frequently all that is available or can with practicability be made available in some very poor and sparsely settled districts.

The experience of the Commonwealth Fund would indicate, however, that there are many rural districts where a good community hospital of from forty to fifty beds could serve a reachable population group of sufficient size, where the nucleus at least of a satisfactory medical staff is available and other trained personnel are obtainable. We have assisted in providing such plants in eleven instances in almost as many states. We believe that they have been of great service and we know that many other similar districts are to be found.

In choosing the location for such hospitals it is important not only to avoid overlapping service areas and consequent unnecessary duplication of facilities but to relate the location of one hospital to that of others and so far as possible to key the community hospitals with the facilities of large urban medical centers and teaching centers. Such arrangements when practicable will create the possibility of informal affiliations, which contribute much in the way of consultant service, educational opportunity and the provision of skilled care for certain patients whom even a good community hospital may not be able to treat adequately. To hospitalize a given state will require careful study and planning if such advantages are to be secured.

I have been considering the hospital in this paper only as providing proper care for the sick. The value of a really good community hospital as a means and channel of education of physicians, nurses and of the public at large has not been dwelt on. In the hospitals with which the Commonwealth Fund has been concerned, the value of organization of the medical staff, of the contact and consultation between physicians, of regular staff meetings for discussion of cases and methods, of consultant pathologic service, of more formal medical institutes and clinical demonstrations, of postgraduate fellowships, of the constant interchange of ideas—these values I can only mention and refer you to a paper by Dr. Lester J. Evans,[4] medical associate of the Commonwealth Fund, read before this body a year ago. As Dr. Evans said, "Such a hospital makes its contribution to education simply by being the kind of hospital it is. In it the doctor finds opportunity for professional growth by learning from what he does and by hearing about what others do. The educational value of this experience is what the doctor makes it."

There is need for many more such hospitals in the United States. No hospital of lesser quality, in my judgment, is worth the having or worth the cost. And it is worth while to note and ponder the following statement by the Catholic Hospital Association:

> The Association is sympathetic with the plan of providing hospital facilities in those areas of the country in which such facilities are not found at the present time, or in which hospital facilities are relatively inaccessible. It cautions, however, against a precipitate and indiscriminating multiplication of hospitals

4. Evans, L. J.: The Rural Hospital, J. A. M. A. 110:945 (March 26) 1938.

and would recommend that the erection of new hospitals . . . be not stimulated except when a prudent prevision of the hospitals' operation and when, furthermore, an adequate staff, medical and administrative, can be provided, with due attention to both the economic and the professional viewpoint.[5]

Those words are in my judgment absolutely sound. Provision of adequate funds to erect, equip and operate community hospitals where they are needed, where they will be utilized, where they can be operated with reasonable economy and where adequate medical and other professional service is available is much to be desired. But intelligent planning, thoughtful foresight, wise administration, physicians of first quality, trained in modern medicine, and other trained personnel—these things are prerequisite to the successful expenditure of funds, large or small. No medical or health ideal, so far as hospitalization is concerned, is obtainable, nor is any measurable advance in that direction obtainable, in any other way.

THE RELATION OF ANESTHESIOLOGY TO MEDICAL EDUCATION

RALPH M. WATERS, M.D.
HUBERT R. HATHAWAY, M.D.
AND
WILLIAM H. CASSELS, M.D.
MADISON, WIS.

This paper has been written to emphasize the need for undergraduate and graduate instruction in anesthesiology and to describe ways and means of its accomplishment.

Recent advances in medicine have widened the scope of anesthesiology to include problems which were only dreamed of twenty-five years ago. The insistence of patients on complete abolition of pain has made more prevalent the use of depressant drugs and the administration of such drugs in larger doses. There results a necessity for clinicians especially trained in the administration of pain-relieving drugs and the management of depressed states. For reasons too numerous to discuss fully here, the medical profession finds itself in the anomalous position of having an obvious lack of clinicians trained in anesthesiology and having scant provision for such training in our medical schools and hospitals.

OBJECTIONS

The following six arguments against clinical instruction are so frequently advanced as to warrant reference to them in some detail: 1. A sufficient number of physicians will not be interested. 2. Present day excellent instruction in the basic science departments makes clinical instruction in anesthesia superfluous. 3. "A little knowledge is a dangerous thing." 4. The medical school curriculum is already overcrowded. 5. The economic adjustments necessary for instruction and the employment of physicians specializing in anesthesia are impossible. 6. The administration of anesthetics is an art, not a science, and as such may be done quite as well by one without scientific training. Each of these six opinions is probably honestly held by some persons and should be honestly answered.

1. The impression that a sufficient number of physicians will not be available is erroneous. Young doctors will show interest in proportion to the inspiration which is imparted to them. The practice, so common at present in many of our medical schools, of delegating not only the technical administration of anesthetics but also the clinical teaching to persons without professional qualifications does not stimulate the interest or respect of the medical student and hospital intern. Conversely, it is noticeable that applications for residencies in anesthesia in hospitals come in higher proportion from Canada and from districts in this country where the administration of anesthetics is limited to graduates in medicine. In centers where professional training has become recognized, there is ample demand for positions. Furthermore, the professional and financial success of others in the specialty adds to its appeal. Recognition of the anesthesiologist as a specialist in certain phases of medicine and therefore as a valuable consultant to other departments adds to the attractiveness of the specialty. Such recognition has been withheld only because of improper teaching and lack of example.

2. The contention that all necessary instruction in anesthesia is provided by good courses in physiology, biochemistry and pharmacology can be based only on an entirely inadequate conception of the clinical importance and relationships of anesthesiology. Careful consideration will show that clinical interpretation and application of basic science knowledge is admittedly necessary in every other branch of medical education. Anesthesiology deserves no less clinical interpretation. It deals with the management of patients acutely depressed by drugs, with artificial respiration, resuscitation, the maintenance of free air passages, the administration of oxygen and other gases, and with the recognition of evidences of oxygen want and carbon dioxide excess, to mention but a few of its ramifications. Many circumstances of depression due to accident or illness bring about changes in the body similar to those accompanying anesthesia. In the medical or surgical wards, however, such disturbances take place over a period of hours or often days, whereas in the operating room they develop often in a matter of minutes and can be followed through cause, development and treatment in a single teaching period. Here then is the ideal place to teach these fundamentals to the student. In later practice, whether he becomes a specialist or a general practitioner, he will have daily use for this knowledge.

3. The dean of a great school has offered as an excuse for complete absence of clinical instruction in anesthesia from his curriculum the quotation "A little knowledge is a dangerous thing." This argument is quite as applicable to the clinical teaching of surgery or any other portion of medical practice. The argument has two obvious fallacies: 1. Lack of clinical teaching will not prevent graduates in medicine from considering themselves competent to deal with matters of anesthesia. Thus by its own standards the argument fails. The minimum of knowledge is already assumed by the medical graduate; therefore he is dangerous; therefore the school should amplify his knowledge as much as possible, at least to the extent of showing him his limitations. 2. The fundamentals of anesthesia are matters of everyday application in every branch of medical practice and therefore cannot be omitted. Training in anesthesiology will amplify a little knowledge gained in other departments and make the young graduate a safer rather than a more dangerous practi-

5. Hospital Progress **19**: 387 (Nov.) 1938.

From the Department of Anesthesia, University of Wisconsin Medical School.

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 14, 1939.

tioner. Whether students are to administer anesthetics or not, they should go out from medical school prepared at least to care for patients while they are subject to drug depression, sometimes induced by an overdose. Physicians must in all justice be possessed of sufficient knowledge of the clinical use of anesthesia to recognize the good from the bad. They should be able to save a life by reestablishing a patent airway or performing efficient and safe artificial respiration when necessary. That some recent graduates are dependent on the fire or police department or on their boy scout manuals for artificial respiration is a serious reflection on present day medical education.

4. That the curriculum is too crowded to include clinical anesthesiology is more apparent than real. Even without formal lecture periods the student, patient and anesthetist can constitute a teaching unit in ward or operating room. When the department was established at the University of Wisconsin twelve years ago there appeared to be no time available for lectures. However, the first year one hour was assigned, the next three hours and the year following six hours. With the present arrangement, to be described later, the curriculum seems no more crowded than twelve years ago. It is apparent therefore that, once the need is appreciated, available time will be found.

5. That no money is available for the establishment of a department of anesthesia on a professional basis may temporarily be true in some institutions. Medical progress modifies budgeting and may involve an added outlay for equipment, replacements and other changes. A well qualified director of anesthesia, who is capable of filling with credit the chair in the faculty of the medical school, should command an income comparable to that of other members of the staff. In the light of the increased scope of the service rendered, necessary budgetary adjustments are insignificant. In some institutions ill advised purchases, lack of attention to home construction of apparatus, and waste of materials have increased costs. With proper reorganization certain economies may result. The change has actually been made in some institutions with a definite financial saving within the first three year period.

6. There can be no question that the administration of anesthetic drugs is an art just as is the skilful handwork of the clever surgeon, but it is an art in the application of fundamental principles of basic science. The minute to minute necessity for the utilization of knowledge of physiology, of pharmacology, of biochemistry, of anatomy and even of physics is appreciated by every keen anesthetist. The rapidity with which changes may occur and the need for accurate thinking and prompt judgment are not exceeded elsewhere in medical practice. The trained anesthesiologist is a scientist applying scientific knowledge of respiration and circulation both in the operating room and in the wards. Art in anesthesia, to be safe for the patient, must be based on a scientific foundation quite as broad and fundamental as is the foundation for the art of surgery.

CONTRIBUTIONS TO GENERAL MEDICAL EDUCATION

Whatever type of practice they expect to pursue, young physicians must go out with sufficient knowledge of clinical anesthesia to recognize its limitations and its possibilities. Somewhere in the medical curriculum, students must be provided the opportunity to correlate the basic pharmacologic facts regarding depressant drugs with their clinical application. They must be taught the proper management in the wards of patients under the influence of such drugs. They must recognize the physiologic and biochemical disturbances which accompany the depression of respiration and circulation as well as have a knowledge of the measures and technics available to correct such disturbances. Such matters can be taught more effectively and more easily during the study and care of the surgical patient before, during and after anesthesia than at any other time.

A series of combined didactic lectures and clinical demonstrations on narcotized patients can be utilized for undergraduate teaching. A laboratory course in surgical technic can be utilized to emphasize the more fundamental principles and to permit experience in open drop technic. During a short period of the fourth year and of the internship the student may serve with the anesthesia department, gaining knowledge through discussion as well as practical experience.

Emphasis is laid on the side effects both of the drugs and of the technic. The principles on which depend the choice of sedative and narcotic drugs and their dosage are discussed, and their administration is demonstrated. Methods of maintaining patent air passages and the treatment of depression are practiced. Indications for and methods of administering pneumotherapy are demonstrated and discussed. Various supportive treatments of depression by rectal, subcutaneous and intravenous routes are discussed and technics of administration demonstrated. The causes and treatment of acute respiratory derangement accompanying and following anesthesia are discussed and demonstrated when possible. The physiologic principles of technic for obstetric pain relief and the physiologic and biochemical balance in the mother as an influence on the condition of the child at birth are stressed. During the administration of pain-relieving drugs to women in labor, the anesthetist has an ideal opportunity to impress on students the fundamental physiologic interrelationship between mother and fetus and the influence which he may exercise on the condition of the fetus by the judicious or injudicious administration of gases or other drugs to the mother. The physical state of patients before operation and their postoperative course in the light of the effects of drugs is studied and recorded by both the senior student and the intern. Such a course of supervised instruction and experience we believe essential in the general medical education of every young physician.

In anesthesiology, as in almost all phases of teaching, service and instruction go hand in hand. Consciously or unconsciously, the student imitates the instructor's service to others and emulates his success. Seeing the anesthetist approach patients with judicious recognition of the problems in medicine and psychology which they present, the student will realize the seriousness of assuming responsibility for the patient's life while administering drugs the therapeutic doses of which range from 65 to 90 per cent of the lethal doses. The student observes that the patient's welfare is the constant concern of the anesthetist and that by means of frequent observations and accurate detailed records the anesthetist can note minute to minute changes, can interpret and assess their significance, can adjust his own course accordingly and can consult with the surgeon should circumstances require a change in the planned procedure. If the student should become a surgeon, he will benefit by knowing to what extent he may rely on the cooperation and advice of the anesthetist

and to what extent he may feel free to attend to the operative procedure without being concerned about the anesthesia. If the anesthetist is qualified to assume complete responsibility for the general condition of the patient, the surgeon's attention may be devoted entirely to teaching and carrying out the surgical procedure, more time may be spent allowing the surgical neophyte to obtain some practice and the young surgeon may be permitted more safely to take the full responsibility for many surgical procedures.

SPECIALISTS

One can hardly start a discussion of the training now required to qualify as an anesthesiologist without first commenting on the debt the profession owes to the many self-taught specialists who have pioneered in this neglected field. Starting with the object of providing patient and surgeon with the best available conditions during operations, many physicians have, through years of service, coupled their extensive experience with a scientific attitude of observation and inquiry to build the practice of anesthesiology into the science it is today. They have contributed the numerous developments which now make intensive training almost obligatory before a younger man can call himself their equal. That these self-taught anesthesiologists still constitute the backbone of the specialty is evident from the fact that only three of the nine members appointed to the American Board of Anesthesiology have qualified by way of formal postgraduate training.

With the larger conception of anesthesia service coming to recognition at this time, it would seem that within a few years any hospital of 100 beds or more with an average proportion of surgical work will need the full time of at least one specialist in anesthesia to perform the various duties connected with a complete service. The qualifications of such a specialist should equal those necessary for certification by the American Board of Anesthesiology, an affiliate of the American Board of Surgery. To qualify for the examination of this board at present, a physician must be of good moral character, of ethical standing, a member of the American Medical Association, licensed by law to practice medicine, a graduate of a grade A medical school, a former hospital intern and a specialist of at least four years' standing, two years of which should have been spent in intensive graduate study. After 1941, in the opinion of the board, the special preparation should consist of six years' specialization, three of which should be spent in thorough training "in the clinical phases of anesthesiology and in anatomy, physiology, pharmacology, biochemistry and other basic sciences which are necessary to proper understanding of the problems involved in the specialty of anesthesiology." Such instruction must have been received in institutions approved by the Council on Medical Education and Hospitals.

The recent rapid increase in the number of institutions offering adequate training and the number and qualifications of the applicants are most encouraging. It may be asked what is to become of these physicians after they finish their training. Placing young specialists in the United States has so far not proved difficult. The demand on the part of medical schools and large teaching hospitals has exceeded the supply. Eventually a saturation point of teaching positions will of course be reached. However, several obvious circumstances will bring about satisfactory adjustments. Established departments tend to expand in scope, requiring an increasing number of associates and assistants. Many men are intensely interested in anesthesiology but not in teaching as a major interest or in research activities. Although they are quite as capable as the teachers, their preference is for private practice in hospitals without university affiliations. The minimum amount of instruction to the house staff necessary in such hospitals is given willingly by these men just as it is by attending staff members in other specialties. The fact that hundreds of physicians who had little or no formal training in anesthesiology, either graduate or undergraduate, have succeeded in such practice in the past proves that there will be abundant need for well trained practitioners in the future.

RESEARCH

It should be emphatically stressed that research is merely a by-product of a department of anesthesiology. First and foremost should come good service to patients, then teaching and finally, when these are assurred, research.

The physical signs induced by, the character of the response to, and the effective dose of anesthetic and depressant drugs are not the same with animals as with man, yet the laboratory is the logical starting point for any physiologic or pharmacologic investigation which may ultimately receive clinical study and final evaluation. Several recent advances in anesthesiology serve to emphasize that cooperative effort between the laboratory worker and the clinician is essential. In addition to purely clinical research, the anesthetist is capable of contributing much toward the satisfactory amalgamation of laboratory and clinical data through discussion of the planning of experiments involving anesthesia and cooperative assistance in the laboratory, aid in checking the results of animal experiments with human beings, offering to the basic science departments the opportunity for clinical observation of their problems, carrying clinical problems to the basic science experts for their consideration and investigation, and independent investigations. The control of the patient essential to proper anesthesia provides admirable circumstances for the study of changing bodily function incident to the anesthetized state.

TECHNICIANS

Surgeons have depended and still depend, to a constantly decreasing extent, on technicians for the administration of anesthetics. A reference to this situation is therefore necessary. The aid of the nursing profession has been priceless. The neglect by the medical profession of so important a function has thus been compensated to some extent. It is obvious, however, to one who has spent many years in training others in the technical as well as in the scientific aspects of pain relief that a more appropriate field for the nurse-technician in medicine is to be found in obstetrics and minor surgery, if indeed such technician assistance is necessary. True, one not possessed of a medical background can be taught to do many things in medical practice. However, the minute by minute need for knowledge and judgment in matters pharmacologic as well as physiologic is rarely so great in normal obstetrics and during certain surgical procedures as it is during the administration of a majority of anesthetics. Decisions during delivery of a parturient woman or during the removal of an appendix are seldom so likely to affect directly

the later incidence of morbidity or even mortality as are the decisions which must be made and acted on during the management of the anesthetized patient. If a technician must be used—and the present need in some localities is admitted—a physician well versed in anesthesiology should be constantly close at hand. The practice, current in some medical schools, of training nurses as anesthetic technicians and sending them out to administer anesthetics without supervision is perpetuating an unjustifiable hazard.

Our experience has taught us two important facts. 1. The employment of anesthesia technicians in a hospital seriously embarrasses the satisfactory training of medical students and doctors. 2. The average intern, after good training in the basic sciences and a half year of reliable undergraduate instruction in the clinical use of anesthesia, can, at the end of a month of carefully supervised practical experience in the operating room, be trusted with the welfare of an anesthetized patient more safely than can the average technician after years of experience. This statement is made advisedly and after long observation of persons working in both categories.

ESTABLISHMENT OF A DEPARTMENT

In what does a department of anesthesiology in a medical school consist? First and without doubt there must be a director, a physician who is the best possible clinical anesthetist as well as teacher. Progress will be more satisfactory if the director's time is devoted solely to one institution. His income should be adequate to maintain him on a par with the heads of other departments. Immediate need for assistants will depend on local circumstances and the size of the hospital. Once such a director is a part of the faculty and hospital staff, gradual development of a department in the hospital and in the school should take place. The basis of both teaching and research is good clinical anesthesia. The director's time during the first year therefore should be concerned mainly with learning the ways of the surgical staff and the staffs of other departments and fitting himself to supply their individual needs. During the director's second year, a short course of lectures and demonstrations to undergraduates can advantageously begin. If the curriculum is hopelessly crowded, possibly an hour can be offered here and there from some branch of surgery or from obstetrics. Gradually the need will become more apparent and the time will become available. As soon as possible, one or two fourth year students at a time should be assigned in rotation to clinical anesthesia. A student will learn more during one week full time than during three weeks part time. The same is true of interns. The longer the period of contact, the better will be the result. During the director's second year, residencies in anesthesia may be thought of, the number depending on the size of the hospital. Only after the clinical work is running smoothly, with the full confidence of the surgical staff, can undergraduate teaching, then graduate teaching and finally research be undertaken.

A SAMPLE DEPARTMENT

The department at the University of Wisconsin as constituted at present will be described, not because it approaches the ideal but because we are familiar with it. Organizations in existence for a shorter time are already more nearly ideal. Some of these have been initiated in hospitals connected with medical schools,[1] while others are in hospitals without teaching affiliations.[2]

This department may be outlined as follows:

A. Personnel
1. Professor of anesthesia in medical school and director of anesthesia, university hospitals; full time; salary from medical school and fee privileges for private patients
2. Instructor in anesthesia: former resident; salary from medical school
3. Research fellow: former resident; salary jointly from research fund and hospital. It is hoped to make two or three permanent associates in the future
4. From five to seven residents: duration of appointment three years; prerequisites M.D., rotating internship and preferably one year residency in internal medicine or two in general practice; stipend and maintenance similar to those of other departments
5. Interns; spend one month in the anesthesia service
6. Fourth year medical students; one week full time; fifty students in each class

B. Teaching
1. Undergraduate
   (*a*) One lecture, second year (courtesy of the pharmacology department)
   (*b*) Course in surgical technic and anesthesia (given to one half of the third year class each semester)
   Instructor and two residents supervise anesthesia and teach fundamentals of open drop ether and chloroform anesthesia with dogs
   Twenty three-hour laboratory periods a year
   (*c*) Sixteen lectures second semester of third year, one hour periods
   Demonstration-lecture usually with anesthetized patient; quiz
   (1) History, terminology and scope of anesthesiology
   Review of Fundamentals of Physiology
   (2) Circulation
   (3) Prophylaxis and treatment of circulatory disturbances
   (4) Respiration
   (5) Prophylaxis and treatment of respiratory disturbances
   (6) The autonomic nervous system
   Review of Fundamentals of Pharmacology
   (7) Nonvolatile agents and correctives
   (8) Gases and vapors (including fire hazard)
   Fundamentals of Technic
   (9) Oral, rectal, subcutaneous and intravenous technics
   (10) Open drop technic; signs of anesthesia
   (11) Carbon dioxide absorption technic
   (12) Other inhalation technics (partial rebreathing, etc.)
   (13) Physiology, pharmacology and technic of obstetric pain relief

Fundamentals of Local and Block Anesthesia

(14) Pharmacology, principles, toxicity (prophylaxis and treatment)

(15) Block technics: emphasizing simple field blocks and spinal blocks

(16) Therapeutic and diagnostic procedures with anesthetic drugs

(*d*) Each fourth year student for one week full time with department; preoperative check of patients scheduled for operation; operating room work; postoperative check of patients; record keeping

2. Postgraduate

(*a*) Intern, twelve of house staff, one month each full time

(*b*) From five to seven residents, three year periods

First and third years, clinical anesthesia with some teaching experience and research

Second year, research major interest (anesthesia problems) with courtesy contact in laboratories of pharmacology or physiology, or clinical research

Trial being made of a limited number of six month appointments of graduates already practicing anesthesiology who wish a postgraduate course; not yet established; if adopted, tuition will have to be charged

(*c*) The department is open to visiting physicians at all times, though no clinical experience is offered such visitors

C. Departmental meetings

(*a*) Current literature review and discussion, two hour session, Monday 7 p. m.

One member reports each week on journals assigned to him; 106 journals covered, with occasional articles from others

A small departmental library maintained; medical school library near at hand

(*b*) Clinical work: Review of past week's cases, including deaths of surgical patients; two hour session, Wednesday, 1 p. m.

Meetings attended by whole anesthesia staff, including intern, student and visitors; chairmanship, in rotation, by residents

(*c*) First year residents required to attend all undergraduate lectures

(*d*) All members of the department expected to attend hospital staff meetings, including clinical-pathologic conferences and university medical meetings

Preoperative rounds are made each evening, when the clinical records of patients are reviewed and transferred to departmental record sheets; after the patients are seen, orders are written for premedication. Odd hours are utilized by residents and interns to examine records and patients after operation and to complete the anesthetic record. The record sheet is then coded to a Hollerith punch card for permanent filing. All records are sorted yearly and a statistical survey of the work of the department compiled. An effort is made to have each resident write at least one paper and gain experience in lecturing to medical students.

The review of basic science for the resident, aside from his attendance at undergraduate lectures, is accomplished in an entirely informal way. Frequent contact with a skeleton, models and charts in the department aids him in coordinating his knowledge of anatomy with the technic of injection anesthesia. Experimental blocks and dissection of the cadaver are made possible through the courtesy of the anatomy department. Joint research efforts are constantly in progress with the departments of physiology and pharmacology and other basic science groups as well as with the various departments of clinical practice. Constant reference to the literature is stimulated as a result of discussions in the operating room and at departmental meetings. This has seemed sufficient for all practical purposes.

A department of anesthesia must conform to the needs of the institution served. In the plan outlined, two permanent associates with an eventual rank of associate professor are essential for future development. The instructor should be retained on a semipermanent basis. Such a personnel is an essential if the short term (six months) instruction to graduates is instituted.

SUMMARY

By anesthesiology is meant not only the science of the administration of drugs for the comfort of patients during operation but also the management of patients in depression from other causes. Pneumotherapy, intravenous therapy, therapeutic and diagnostic procedures involving the use of anesthetic drugs, and other efforts based on similar scientific knowledge, logically fall within the scope of anesthesiology. Clinical instruction in this subject is sound educational policy in the broad training of every physician. The outline given of the establishment and conduct of such a department in a teaching hospital and medical school is not ideal but may afford a groundwork on which better organizations may be constructed in other medical schools and in the various hospitals. The patient under the influence of pain-relieving drugs, together with the department of anesthesia, constitutes a natural decussation of many of the pathways between basic science and clinical teaching. Appreciation of this relation is, we believe, a contribution to our educational program.

NOTE.—The references cover only the published accounts of established departments of anesthesia. There are many departments, especially of recent origin, which have not been described in the literature.

THE INTRAVENOUS USE OF SODIUM SULFAPYRIDINE

E. K. MARSHALL JR., PH.D., M.D.
AND
PERRIN H. LONG, M.D.
BALTIMORE

The very slight solubility of sulfapyridine (2-[*p*-aminobenzene sulfonamide] pyridine) in water renders parenteral administration of this drug difficult when a route other than oral administration is desired. The poorer and more erratic absorption from the gastrointestinal tract of sulfapyridine as compared to sulfanilamide [1] necessitates its parenteral use in certain cases if high blood concentrations are to be attained. Sulfanilamide is sufficiently soluble to allow the use of subcutaneous administration of a saturated solution in physiologic solution of sodium chloride but in the case of sulfapyridine several liters of fluid would have to be given. Whitby [2] has suggested the injection of an oil suspension of sulfapyridine intramuscularly. There are objections to this procedure and even possible dangers.[3] The very soluble sodium salt of sulfapyridine recently described and studied by Marshall, Bratton and Litchfield [1] would appear to offer a means of parenteral administration of the drug.

This investigation has been aided by a grant from the John and Mary R. Markle Foundation and a grant from the Chemical Foundation, Inc., of New York.

From the Department of Pharmacology and Experimental Therapeutics and the Department of Medicine, Johns Hopkins University School of Medicine.

1. Marshall, E. K., Jr.; Bratton, A. C., and Litchfield, J. T.: Science **88**: 597 (Dec. 23) 1938. Long, P. H., and Feinstone, W. H.: Proc. Soc. Exper. Biol. & Med. **39**: 486, 1938.
2. Whitby, Lionel: Lancet **2**: 1095 (Nov. 12) 1938.
3. Long, P. H.: Lancet **1**: 60 (Jan. 7) 1939.

Since a solution of sodium sulfapyridine is strongly alkaline (p_H 10.4 to 11.0), the only possible route of parenteral administration is the intravenous one. The p_H of such a solution is somewhat higher than that of a sodium salt of a barbiturate [4] and lower than that of alkalinized arsphenamine,[5] but the total amount of alkali given at a dose would be greatest in the case of sodium sulfapyridine. With the experience of intravenous injection of barbiturates and arsphenamine as a background, it seemed proper to use sodium sulfapyridine intravenously as an emergency measure if animal experimentation on its acute toxicity by this route seemed to justify its clinical trial. Since any delayed toxic effects and chronic toxicity from the intravenous use of sodium sulfapyridine must obviously be identical with these effects produced by the same blood concentrations of sulfapyridine administered orally, we have investigated in animals only the acute toxicity of sodium sulfapyridine by intravenous injection. The following data are taken from an unpublished study of Marshall and Litchfield on certain aspects of the pharmacology of sulfapyridine.

TABLE 1.—*Toxicity of Sodium Sulfapyridine for Dogs*

Dog	Dose, Gm./Kg.	Per Cent Solution Injected	Blood Level Mg. per 100 Cc. 1 Hour After	Symptoms
A	0.1	10	10.0	None
B	0.1	5	11.1	Vomited once
B	0.1	10	11.3	Vomited once
B	0.1	20	10.9	None
C	0.1	20	17.1	None
D	0.1	20	9.7	None
E	0.1	5	10.5	None
F	0.2	10	24.2	Slight ataxia
C	0.2	10	20.8	Slight muscular twitching
G	0.2	10	22.3	Slight muscular twitching and ataxia
H	0.2	10	20.4	None
I	0.3	20	37.8	Vomiting, muscular tremor and convulsions
J	0.3	20	36.5	Vomiting, convulsions, muscular tremors
K	0.5	20	55.5	Vomiting, convulsions, died in 6-10 hours
L	0.5	20	60.6	Vomiting and convulsions
M	0.5	20	52.8	Vomiting and convulsions
N	0.5	20	58.8	Vomiting and convulsions
O	0.5	20	64.5	Vomiting and convulsions, died in 3 hours

In table 1 is given a summary of the experiments on dogs. The symptoms from an intravenous injection of a solution of the sodium salt are identical with those observed in mice and dogs by Marshall, Bratton and Litchfield [1] after oral administration of this drug. With the exception of slight vomiting in one animal, symptoms were not observed with 0.1 Gm. per kilogram; with 0.5 Gm. per kilogram severe symptoms and convulsions were always seen, and death occurred in two out of the five dogs injected with this dose. Neither the strength of the solution used nor the rate of injection seemed to influence the symptoms, except those seen during the first few minutes, when collapse occurred if the solution was given too rapidly. Blood concentrations [6] were done at intervals on all the animals, but those taken at about one hour (from forty-five to sixty minutes) after injection are given because at this time equilibrium between blood and tissues is certainly complete and maximum symptoms are seen. One can note the approximate proportionality between dose and blood concentration. In table 2 are summarized data on the intravenous injection of the sodium salt into rabbits. It is clear that rabbits, even on the basis of blood concentrations, are more resistant than dogs; this may be due to the fact that the rabbit acetylates sulfapyridine very rapidly and shows a more rapid fall in blood concentration with time than does the dog, which does not acetylate at all.

On account of the well known effects on circulation and respiration caused by the injection of insoluble organic acids which require a large amount of alkali for solution,[4] the effect of the injection of solutions of sodium sulfapyridine on the blood pressure and the respiration of anesthetized dogs was studied. Under light ether anesthesia, five dogs were given eleven injections of 0.1 Gm. per kilogram of sodium sulfapyridine in either 5 or 20 per cent solution, the time of injection varying from one half to ten minutes. The effect appears to depend on the strength of the solution and the rate of injection. With strong solutions injected rapidly, a marked fall of blood pressure and decrease of respiration occur; with weak solutions injected slowly, practically no change in blood pressure or respiration is observed. Various intermediate reactions between these extremes were observed. In the accompanying tracing the two extremes are shown.

Since it has been shown [7] that when sulfanilamide is injected intravenously or when a sufficiently high concentration in the blood is attained by oral administration renal function is temporarily depressed, the effect of the intravenous injection of sodium sulfapyridine on the creatinine clearance of dogs has been investigated. Three or four control periods were taken to determine the creatinine clearance, an intravenous injection of 0.1 Gm. per kilogram of sodium sulfapyridine was given and the creatinine clearance was measured for several periods during the next two or three hours. No change was observed in the creatinine clearance under these conditions, indicating that in dogs an immediate effect is not produced on renal function by the intravenous injection of this dose of sodium sulfapyridine.

TABLE 2.—*Toxicity of Sodium Sulfapyridine for Rabbits*

Rabbit	Dose, Gm. per Kg.	Per Cent Solution Injected	Blood Level Mg. per 100 Cc. 1 Hour After Free	Blood Level Mg. per 100 Cc. 1 Hour After Total	Symptoms
B	0.3	20	20.5	32.0	None
A1	0.5	10	44.0	54.8	Muscular twitching, mild convulsions
A2	0.5	10	45.1	56.0	Muscular twitching, mild convulsions
A3	0.5	10	45.7	49.1	Muscular twitching
A4	0.5	10	41.1	53.7	Muscular twitching
E	0.5	5	40.0	44.5	Temporary respiratory stoppage, muscular twitching
F	0.5	5	52.3	52.3	Muscular twitching, slight rigidity
G	0.5	5	....	....	None
D	0.5	20	30.6	40.0	None

In view of the foregoing considerations and experimental studies on animals, a careful clinical trial of the intravenous use of sodium sulfapyridine was undertaken. It seemed that a dilute solution of the sodium salt should be used and injected fairly slowly. A 5 per cent solution in sterile distilled water was chosen. On the basis of no ionization of the salt this would be slightly hypotonic, while on the basis of complete ioniza-

4. Intravenous Use of Barbital Compounds, Report of the Council on Pharmacy and Chemistry, J. A. M. A. **97**: 1886 (Dec. 19) 1931.

5. Elvove, Ephraim, and Clark, W. M.: Bull. 135, Hyg. Lab., U. S. P. H. S., March 1924.

6. Determinations of sulfapyridine in blood were done by diazotization and coupling with *N-(1-naphthyl)ethylenediamine*. A 1:50 or 1:100 dilution was used and readings were made with a photoelectric colorimeter (Bratton, A. C., and Marshall, E. K., Jr.: J. Biol. Chem., to be published).

7. Marshall, E. K., Jr.; Cutting, W. C., and Emerson, Kendall, Jr.: The Toxicity of Sulfanilamide, J. A. M. A. **110**: 252 (Jan. 22) 1938

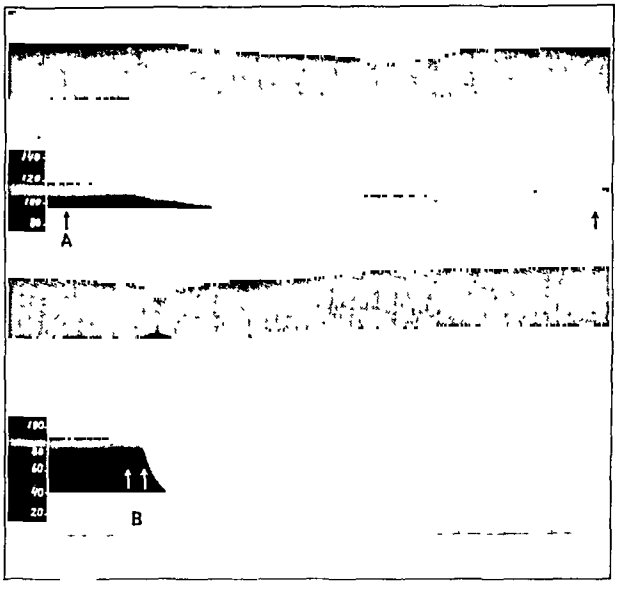
tion it would be slightly hypertonic. In point of fact it is probably isotonic or very nearly so. The p_H of this solution is from 10.7 to 10.8. Since the sodium salt used [8] contained a molecule of water of crystallization, 3.8 Gm. of the salt for a patient weighing 65 Kg. would be equivalent to 0.05 Gm. per kilogram of sulfapyridine; 3.8 Gm. was the standard dose adopted for adult patients.

Injections of sodium sulfapyridine have been given to thirty patients. No symptoms of untoward effects have been noted in any case except vomiting during or immediately after the injection. No respiratory or acute circulatory disturbances were apparent during or immediately after the injection. No abnormality was observed in the routine examination of specimens of urine taken after the injection. It is interesting to note that vomiting is produced in both dogs and human subjects when sulfapyridine is given intravenously, so that the hypothesis of gastric irritation as its cause must be questioned. Determination of blood concentration values at various times after injection were made in fifteen injections in ten patients. The summary of the histories of these ten cases are given:

REPORT OF CASES

CASE 1.—W. D., a Negro aged 46, entered Johns Hopkins Hospital Feb. 9, 1939, suffering from type III pneumococcus lobar pneumonia which involved the greater part of both lung fields. The blood culture was negative. Treatment was instituted by administering sulfapyridine orally. On the day after entry the temperature was still elevated. Sodium sulfapyridine was given by the intravenous route at 8 p. m. February 10 and again February 11. The oral administration of sulfapyridine was continued as before. The patient made an uneventful recovery and was discharged February 28.

CASE 2.—J. S., a white man aged 20, entered Johns Hopkins Hospital Feb. 16, 1939, suffering from type II lobar pneumonia which involved the left lower lobe. The blood culture was negative. Sulfapyridine was administered by mouth, but because of a recrudescence of fever February 18 and the fact that the "free" blood sulfapyridine was only 2.7 mg. per hundred cubic centimeters, sodium sulfapyridine was administered by the intravenous route at 2 p. m. and 8 p. m. that day. The patient made an essentially uneventful recovery, which was marred only by a sterile pleural effusion which developed February 25 and required paracentesis on two occasions before it disappeared. He was discharged March 10.



CASE 3.—C. W., a Negro aged 35, entered Johns Hopkins Hospital Feb. 20, 1939, suffering from type IV pneumococcus lobar pneumonia involving the right upper and left lower lobes. The blood culture was negative. Treatment was started with sulfapyridine by mouth. On the morning after entry to the hospital his temperature was still elevated and the level of sulfapyridine in the blood was 2.9 mg. per hundred cubic centimeters. He was therefore given the sodium salt of sulfapyridine by the intravenous route. Sulfapyridine was continued by mouth. On the eighth day the drug was discontinued because a moderate leukopenia and neutropenia developed. Recovery, however, was uneventful and he was discharged March 9.

CASE 4.—M. F., a white woman aged 47, entered Johns Hopkins Hospital Feb. 26, 1939, suffering from type III pneumococcus lobar pneumonia involving the right middle lobe. The blood culture was negative. The patient appeared quite ill. Treatment was begun with sulfapyridine administered by mouth. On the following day the temperature was elevated and the level of the sulfapyridine in the blood was 2.9 mg. per hundred cubic centimeters. She was given one intravenous injection of sodium sulfapyridine. Oral medication with sulfapyridine was continued and the patient made an uneventful recovery. She was discharged from the hospital March 12.

8. We are indebted to Dr. Randolph T. Major of Merck & Co. for a supply of the sodium salt and to Dr. K. K. Chen of Eli Lilly & Co. for the sodium salt in sterile ampules for intravenous injection.

CASE 5.—I. F., a white woman aged 38, entered Johns Hopkins Hospital Feb. 25, 1939, suffering from type III lobar pneumonia involving the right upper, middle and lower lobes. She appeared to be quite ill and showed marked distention. The blood culture was negative. Treatment was instituted by the administration of sulfapyridine by mouth. February 26 no great improvement was noted and the patient was given 3.8 Gm. of sodium sulfapyridine by the intravenous route. Medication by mouth was continued and the patient made an uneventful recovery, being discharged from the hospital March 18.

CASE 6.—G. S., a Negro aged 32, entered Johns Hopkins Hospital Feb. 4, 1939, suffering from primary type VIII pneumococcus peritonitis with bacteremia. The blood culture showed one colony of type VIII pneumococcus per cubic centimeter of blood. An exploratory laparotomy and appendectomy with drainage was done. The appendix was subsequently found to be normal. Treatment was instituted February 5 with sulfapyridine in a 0.1 per cent solution by the intravenous route. On the following day 3.8 Gm. of sodium sulfapyridine was given by the intravenous route and this dose was repeated February 7. Treatment with sulfapyridine by mouth was begun February 8. The patient's recovery was uneventful and he was discharged from the hospital February 23.

Effect of intravenous injection of sodium sulfapyridine on blood pressure and respiration of dogs anesthetized with ether. In *A*, upper curve shows respiration, lower curve mean blood pressure. In *B*, upper curve shows respiration, middle curve mean blood pressure, lower curve time in minute intervals. Time tracing applies for both *A* and *B*. In *A*, between the two arrows, slow intravenous injection of 0.1 Gm. per kilogram of sulfapyridine in the form of a 5 per cent solution of its sodium salt. In *B*, between arrows, rapid intravenous injection of 0.1 Gm. per kilogram of sulfapyridine in the form of a 20 per cent solution of its sodium salt.

CASE 7.—M. S., a Negress aged 50, entered Johns Hopkins Hospital Feb. 6, 1939, suffering from type III pneumococcus lobar pneumonia involving the left upper and lower lobes. Treatment with type III antipneumococcus rabbit serum was started. A blood culture taken February 6 was negative but one taken February 8 showed twenty-one colonies of pneumococcus type XVI per cubic centimeter of blood. February 8 3.8 Gm. of the sodium salt of sulfapyridine was administered twice by the intravenous route and was repeated by the next day. Oral medication with sulfapyridine was commenced February 9 and continued until February 18. Recovery and convalescence were uneventful. The patient was discharged from the hospital March 7.

CASE 8.—H. H., a Negro aged 30, entered Johns Hopkins Hospital Feb. 25, 1939, suffering from type I lobar pneumonia involving the right lower lobe. He appeared to be very ill. The blood culture showed type I pneumococci. Treatment was instituted by the intravenous administration of sodium sulfa-

pyridine and was continued on the next day by giving sulfapyridine by mouth. The drug was discontinued on the fifth day of treatment because an acute hemolytic anemia developed. Recovery, however, was uneventful, and the patient was discharged March 13

Cases 9 and 10 were essentially negative.

COMMENT

In table 3 certain additional data concerning these patients are given. The dose per kilogram is expressed in terms of sulfapyridine, the values for blood concentrations before and at various times after the injection in terms of sulfapyridine, the first figure representing the free and the second the total. In the first five cases it is to be noted that the blood concentration values represent the effect of oral as well as intravenous administration. The blood pressure was taken just before the injection and again as soon as the injection was completed. The figures for blood concentrations at various times after the injection emphasize certain important facts. It is obvious that distribution between blood and tissues is complete or nearly complete from five to ten minutes after the completion of the injection, as very little decrease occurs in these values for the next hour. The blood concentration is remarkably well sustained after a single intravenous injection, and in this respect the human subject resembles the dog more than the rabbit. One notes that the blood concentration of total sulfapyridine at one hour after injection has been from 5 to 8 mg. per hundred cubic centimeters higher than before injection; the increase in the concentration of the free form is about the same, indicating that little or no acetylation takes place in the first hour. By the fourth hour conjugation of the injected drug has begun, but in cases 3 and 8 practically no acetylsulfapyridine is present.

The intravenous use of sodium sulfapyridine is advantageous in that blood levels of from 5 to 8 mg. per hundred cubic centimeters can be attained with great speed and certainty. Not only in cases in which administration of sulfapyridine by mouth is impossible or in which intestinal absorption is very poor, but also in cases in which prompt action of the drug is imperative, the intravenous route is advisable. On the other hand, the potential dangers associated with intravenous medication in general and especially with strongly alkaline solutions of weak acids such as arsphenamine and the barbiturates must not be forgotten.[4] Hence the intravenous use of sodium sulfapyridine should be limited to conditions in which oral administration is impossible or does not suffice for successful therapy.

Since our use of the intravenous injection of sodium sulfapyridine has been confined to pneumococcic infections, a statement of our present practice in treating pneumococcic lobar pneumonia with sulfapyridine may be given here.

In mildly or moderately ill adult patients it is our practice to administer an immediate dose of 4 Gm of sulfapyridine by mouth. Then maintenance doses of 1 Gm. of the drug are given orally at intervals of four hours until the patient's temperature has been normal for at least forty-eight hours. The dose of the drug is then reduced to 1 Gm. every six hours and this regimen is continued until resolution of the pneumonic process is well under way, at which point 0.5 Gm of sulfapyridine four times a day is begun and maintained until the lungs are clear.

If, however, the patient seems to be severely ill, the sodium salt of sulfapyridine is given by the intravenous route. The dose is calculated on the basis of 0.05 Gm of sulfapyridine per kilogram of body weight (equivalent to 0.06 Gm. per kilogram of the sodium salt with 1 mole water of crystallization). The drug is made up in a 5 per cent solution in sterile distilled water and is given by the intravenous route. It should be injected slowly at the rate of 5 cc of the solution per minute. Great care should be taken that none of the solution of sodium sulfapyridine gets outside of the vein; otherwise a bad slough may result, as the solution is very alkaline. This dose may be repeated at intervals of from six to eight hours. Sulfapyridine in doses of 1 Gm. every four hours by mouth should be started at the time of intravenous therapy. Rarely have we found it necessary to give more than two injections of sodium sulfapyridine.

We also employ the solution of the sodium salt of sulfapyridine in the treatment of patients with pneumonia who are not responding to therapy by mouth because of poor absorption from the gastrointestinal tract. If on the day following the beginning of sulfapyridine treatment by mouth the patient's temperature is not below 101 F. rectal and the concentration of free sulfapyridine in the blood is below 4 mg. per hundred cubic centimeters, a single dose of 0.06 Gm of the sodium salt per kilogram of body weight in a 5 per cent solution is administered by the intravenous route. The oral administration of sulfapyridine is continued according to schedule. In our experience this has resulted in prompt return of the temperature to normal.

TABLE 3.—*Data on Intravenous Injection of Sulfapyridine in Patients*

* The first figure in each column represents free, the second figure total

The intravenous use of the sodium salt is also of value in the treament of patients who are vomiting. Nausea and vomiting may still occur, as has been stated previously, but, because the drug is being given intravenously, effective blood levels may be maintained. We are not certain as to what concentrations of the drug in the blood are most effective. Our experience leads us to believe that a level of 4 mg. per hundred cubic centimeters or more is desirable in pneumonia of adults.

ACUTE MYOCARDIAL INFARCTION NOT DUE TO CORONARY ARTERY OCCLUSION

CHARLES K. FRIEDBERG, M.D.
AND
HENRY HORN, M.D.
NEW YORK

It is well known that the clinical and electrocardiographic features of coronary thrombosis may be observed in patients in whom a coronary artery thrombus is subsequently not found at necropsy. In such patients the clinical picture may have been caused by a myocardial infarct in the absence of a coronary artery occlusion. The occurrence of recent myocardial infarction without acute coronary thrombosis has been noted by Libman,[1] Oberndorfer,[2] Büchner,[3] Hamburger and Saphir,[4] Dietrich,[5] Levy and Bruenn[6] and others.[7] We have therefore undertaken a detailed systematic study of the myocardium and of the coronary vessels in order to determine the relative frequency of myocardial infarction without coronary occlusion and to discover, if possible, what physiologic factors and what clinical conditions are responsible.

It is theoretically conceivable that myocardial infarction may occur whenever there is severe myocardial ischemia, even in the absence of a mechanical occlusion of the coronary arteries. Severe myocardial ischemia and consequent acute myocardial necrosis may result from a relative inadequacy of the coronary blood flow for the functional demands of the myocardium or from changes in the blood itself. Thus Christ[8] produced disseminated areas of ischemic necrosis in the hearts of animals poisoned by carbon monoxide, while Herzog and others[9] observed areas of degeneration and hemorrhagic myonecrosis in human beings who had been poisoned in this manner. Similar areas of myocardial necrosis have been observed in persons suffering from severe anemia[10] and in animals in which anemia had been produced experimentally.[11] In cases of angina pectoris, either during an attack of spontaneous cardiac pain[12] or during exercise tests,[13] electrocardiographic changes similar to those of coronary thrombosis have been noted. These changes may be attributed to a transient functional insufficiency of the coronary flow with consequent ischemia and even necrosis of the myocardium. Büchner[14] discovered disseminated areas of myocardial necrosis in persons who had had attacks of angina pectoris during the last days of their lives but who had not suffered a coronary thrombosis. Although these isolated observations indicate that myocardial infarction may result from an inadequate coronary blood flow (coronary insufficiency) without coronary occlusion, a systematic investigation of its occurrence in human beings has not yet been reported.

It is now evident that the characteristic electrocardiogram of coronary thrombosis is due not to the thrombosis but to the resulting myocardial infarction, so that the same picture might be expected whether the myocardial injury was caused by a coronary occlusion or by coronary insufficiency. In cases in which there is pulmonary embolism, one often encounters not only a clinical picture[15] but also an electrocardiogram[16] which is identical with that of coronary thrombosis. In a recent study we[17] presented evidence that under certain circumstances pulmonary embolism may induce severe insufficiency of the coronary circulation with consequent myocardial infarction. Although there was no coronary artery thrombus, the myocardial infarct was associated with clinical and cardiographic phenomena ordinarily observed in cases of coronary thrombosis. One of us, with Sohval,[18] also observed myocardial infarction without coronary thrombosis in cases of calcific aortic stenosis (Mönckeberg) and suggested that many of the resemblances of calcific aortic stenosis to coronary sclerosis and thrombosis were actually due to such myocardial lesions. A detailed investigation of this question will be reported later.

The following report of cases of myocardial infarction not due to coronary thrombosis is made both to emphasize the frequency of this condition and to note its relationship to some of the problems already mentioned.

MATERIAL

Thirty-four cases of acute myocardial infarction without coronary thrombosis were observed among the 2,000 autopsies performed at the Mount Sinai Hospital in the last four years. Three of the previously reported cases[18] of calcific aortic stenosis were again studied because they also presented myocardial infarctions without thrombosis. Of the thirty-four more recent cases twenty-eight were observed in the last thousand autopsies, while only six were encountered in the preceding thousand autopsies. This increase is undoubtedly due to a more systematic study of the hearts in the last

few years, during which time we directed special attention to the subject of myocardial infarction without thrombosis. It emphasizes that diligent search is necessary to discover these lesions. In the last thousand autopsies, in which there were twenty-eight cases of myocardial infarction without coronary thrombosis, there were also sixty-three cases of myocardial infarction due to acute coronary thrombosis. Thus, as much as 31 per cent of the total number of cases of myocardial infarction occurred without acute coronary thrombosis (table 1).

TABLE 1.—*Cases of Myocardial Infarction in 2,000 Consecutive Necropsies**

Autopsy Numbers	Total	With Coronary Thrombosis		Without Coronary Thrombosis	
		Number of Cases	Per Cent	Number of Cases	Per Cent
9,001–10,000	62	56	90	6	10
10,001–11,000	91	63	69	28	31

*There were three additional cases utilized from necropsies preceding No. 9,001.

In thirty-two of the total thirty-seven cases, the heart on gross examination presented severe recent myocardial damage. Five other hearts presented microscopic acute myocardial lesions, which were discovered only on systematic study of a series of cases of recurrent pulmonary embolism.

Whenever acute myocardial lesions without recent coronary thrombosis were noted, the main coronary arteries and their branches were studied in detail throughout their course to make sure that a thrombus was not overlooked. In routine postmortem examinations, even when these are carefully performed, a coronary thrombus may be missed. We believe, so far as possible without complete microscopic serial sections, that our systematic study of the coronary vessels excludes the possibility that a coronary thrombus was present. Recent reports[19] and personal observations have shown that many so-called coronary artery thrombi are really occlusions of the coronary arteries secondary to a hemorrhage into an arteriosclerotic plaque. Such occlusions, like primary coronary artery thrombosis, produce myocardial infarction. In none of the cases of myocardial infarction here reported were there occlusions due to hemorrhage within the wall of the coronary artery. Nor were there multiple closures of the small myocardial branches of the coronary arteries. All the hearts were personally examined by us.

Transverse sections were made throughout the entire course of each main artery and its branches, at intervals of 3 mm. Extremely narrowed portions of the vessels or areas that were suspected of being the site of a thrombus were sectioned at even closer intervals and were studied microscopically. Whenever possible, the following branches were carefully examined: the left anterior descending and its primary and secondary rami; the left circumflex and its branches to the anterior wall of the left ventricle, to the obtuse margin of the heart and to the posterior wall of the left ventricle; the main right coronary branch; the right circumflex artery and the branches to the posterior interventricular sulcus and to the posterior wall of the left ventricle, and the branches of the right coronary to the anterior and posterior walls of the right ventricle and to the acute margin of the heart. The branches to the auricles were also examined but were frequently of minute caliber or could not be followed. The degree of arteriosclerosis and narrowing of the various coronary vessels and of the coronary ostiums was graded from one to four plus, according to their severity. The myocardium itself was diligently studied, grossly and histologically, sections being taken from the anterior and posterior portions of the right and left ventricle, of the interventricular septum, of the anterior and posterior papillary muscles and of any additional areas that appeared abnormal. The hearts were also examined for disease of the valves, pericarditis, endocardial abnormalities and mural thrombi.

CLINICAL FEATURES

The clinical features are best presented in groups of cases, according to the various diseases that precipitated or predisposed to the myocardial infarction (table 2). In general, however, the entire series of cases presented one or more of the following clinical pictures: (1) cardiac pain and other clinical and cardiographic signs resembling coronary thrombosis, (2) cardiac failure with or without sudden death, (3) shock and (4) intercurrent diseases unrelated to the heart. Thus, in a general way the clinical pictures resembled those encountered in myocardial infarction due to coronary thrombosis.

The largest group, twelve cases, was associated with recurrent pulmonary embolism. Four of the patients had suffered from hypertension and an equal number from attacks of angina pectoris. In three there were symptoms of congestive heart failure. Five of the patients died in shock. Electrocardiograms had been taken in six of the cases and in three of them the cardiographic abnormalities suggested an acute coronary occlusion.

A second large group included nine instances of calcific aortic stenosis. The patients were all men and, except for one man of 30, were between the ages of 50 and 74. Hypertension was present in four cases and angina pectoris in five. Except for one patient, they were hospitalized because of symptoms of failure of the left side of the heart, to which usually those of failure of the right side were eventually added. In four of the cases death occurred rather suddenly and unexpectedly. Bundle branch or intraventricular block was present in four, and T and RT abnormalities were present in five of the cases. The clinical diagnosis most commonly suggested was coronary arteriosclerosis and cardiac failure. In two a diagnosis of coronary thrombosis had been made.

TABLE 2.—*Clinical Groups of Cases of Myocardial Infarction Without Coronary Thrombosis*

	Number of Cases
Pulmonary embolism	12
Calcific aortic stenosis	8
Coronary narrowing, old occlusion and cardiac failure	6
Postoperative infarction	4
Severe acute anemia	3
Malignant hypertension with cerebral complication	3
Occlusion of superior mesenteric artery	1
Total	37

A third group was composed of six cases in which coronary insufficiency was apparently due to severe

coronary disease itself, without recent occlusion and without any associated valvular or extracardiac factor capable of inducing coronary insufficiency. At least three of the patients had had moderate hypertension. In all but one there was a history of angina pectoris, usually related to effort. Evidence of failure of the right side of the heart was found in all. Usually there was an intensification of the signs of failure shortly before death, or else there was an acute attack of severe and persistent cardiac pain or of pulmonary edema and shock. The electrocardiograms were interpreted as indicative either of myocardial damage or of a previous myocardial infarction. In two cases there were progressive electrocardiographic changes characteristic of recent myocardial infarction.

Four cases were observed in which myocardial infarction appeared after an operative procedure. The ages ranged from 54 to 79. Three were patients with hypertension and diabetes. Two of them had had attacks of acute urinary retention due to prostatic obstruction; one died five days after a suprapubic cystostomy; in the other clinical and cardiographic evidences of myocardial infarction developed in the third week after a similar operation. In a third case, on the second day after operation for a strangulated femoral hernia, the blood pressure dropped from 168 mm. of mercury systolic and 90 diastolic to 110 systolic and 64 diastolic. Transient atrioventricular dissociation developed and she died suddenly on the seventeenth day after operation with symptoms of shock. The fourth patient died three days after a cecostomy for an obstructing carcinoma of the sigmoid colon.

In three cases, myocardial infarction was found in persons who clinically presented a cerebral complication of severe hypertension. In all three the systolic pressure was well above 200 mm. of mercury and the diastolic pressure above 120. During the week before death, evidence of progressive cerebral softening, characterized by a stiff neck, changes in the reflexes and an appearance resembling decerebrate rigidity developed in one patient. The second patient suddenly became unconscious, suffered a hemiplegia and died in pulmonary edema and shock. The third patient, a woman aged 28, presented signs of uremia and acidosis. Eight days before death convulsions developed which were attributed to hypertensive encephalopathy. In none of these cases was there a fall in blood pressure.

In the remaining four cases anemia or shock may have played a role in precipitating coronary insufficiency and ensuing myocardial infarction. One patient was a woman aged 19 in whom in the fifth month of pregnancy a bloody diarrhea developed as the result of ulcerative colitis. Following sulfanilamide therapy her temperature rose to 106 F., the hemoglobin dropped to 15 per cent and she died with symptoms of peritonitis and bronchopneumonia. Sulfanilamide itself has not been found to produce myocardial necrosis. The second patient was a man aged 59 who vomited a large amount of black fluid, became very weak and had several loose, bloody and tarry stools. The hemoglobin fell to 45 per cent. Despite transfusions, acrocyanosis of both hands and feet developed and he went into collapse and died eleven days after the onset of the attack. The third patient was a man aged 78 in whom signs of shock developed as the result of an occlusion of the superior mesenteric artery with infarction of the intestine. The fourth was a man aged 66 with severe acute hemolytic anemia.

PATHOLOGY OF THE HEART

Ordinarily, infarction denotes the morphologic changes, including necrosis, in an organ whose blood supply is interrupted. Technically, therefore, the objection could be raised that the lesions observed in these cases cannot be termed infarcts because there is no actual occlusion of the nutritive vessels. The myocardial changes seen in the cases cited, however, were indistinguishable from those ordinarily described as infarcts and, like infarcts, consisted of areas of necrosis due to ischemia caused by an inadequate coronary blood supply. Occasionally a large confluent area of muscle was affected, similarly to that observed with recent occlusion of a major coronary vessel. More often, however, there were smaller isolated or disseminated foci of myomalacia, recognizable grossly.

The myocardial lesions were, in the main, confined to the wall of the left ventricle and its papillary muscles. The vulnerability of this site has been previously stressed by Büchner.[14] This localization was especially remarkable when, as in a few cases, the acute myocardial damage was entirely or almost entirely confined to one of the papillary muscles of the left ventricle. The anterior wall was affected somewhat more frequently than the posterior, but as a rule there were microscopic lesions in both of these segments of the left ventricle. Another feature of localization of the myocardial lesions is their occurrence in the subendocardial region. This is the portion of the myocardium farthest removed from the blood supply and therefore most severely affected by a relative insufficiency of the coronary flow. The localization of acute ischemic myocardial lesions to the subendocardial region also suggests that the nourishment of muscle fibers through the thebesian vessels is insignificant.

The gross changes varied in severity and extent. They consisted of greenish, yellowish or grayish discoloration of the muscle tissue, which was often streaked or mottled with hemorrhage. Often, however, hemorrhagic areas appeared on microscopic examination to be areas of organization with numerous congested capillaries and other small vessels. Occasionally the gross appearance of the affected myocardium was that of fatty change. Healed fibrous areas were often associated with acute necrosis. In some cases there were extensive fibrotic areas or aneurysms of the heart wall due to an old coronary occlusion.

Microscopic study revealed acute, organizing and chronic lesions. Early evidences of myocardial degeneration consisted of an uneven staining of the muscle fibers with the appearance of darker and lighter eosinophilic bands and loss of myostriation. Signs of more severe ischemic change were vacuolization of the muscle fibers, karyorrhexis or complete disappearance of their nuclei and, finally, homogenization and disappearance of muscle fibers. Sometimes there were large areas of vacuolated muscle fibers and fibrous tissue. In the vicinity of the necrotic muscle there were usually reactive foci of polymorphonuclear leukocytes, lymphocytes and mesenchymal cells[20] and sometimes focal or widespread areas of hemorrhage. Organization occurred early, as indicated by fibroblasts, cellular edematous connective tissue and congested blood vessels.

As a rule the coronary vessels showed extensive arteriosclerotic thickening with narrowing of their lumens. The left anterior descending branch appeared

20. Ehrlich, J. C., and Lapan, B.: The Anitschkow Myocyte, to be published.

to be most frequently and most severely involved, although the circumflex branch of the left coronary and the main right coronary and its circumflex branch were also conspicuously affected. There was no evidence either of intramural hemorrhage or of recent thrombosis of the coronary arteries or their branches. In the group of cases presenting coronary narrowing and failure, without other associative disease, there was almost invariably evidence of an old coronary occlusion. On the other hand, there were several cases in the group presenting pulmonary embolism and isolated instances in the other groups in which the coronary vessels were essentially normal or gave only slight evidences of arteriosclerosis without narrowing (table 3).

Except in a few cases the hearts were markedly hypertrophied and weighed considerably more than normal. However, a number were of normal size. The heart of a 19 year old girl with anemia weighed only 225 Gm. But as a rule the heart weights averaged between 400 and 500 Gm. The largest hearts were those associated with calcific aortic stenosis. The weights ranged between 450 and 1,300 Gm., the average being 710 Gm.

TABLE 3.—*Heart Weight and Degree of Coronary Narrowing*

ILLUSTRATIVE CASES

CASE 1.—*Massive pulmonary embolism* (practice of Dr. Samuel Silbert).

A man aged 58 had for fifteen years suffered pain in the left calf on walking. For two weeks there was pain in both legs even at rest. Occasionally the patient had suffered from precordial pain, which was also worse on exertion. Examination revealed a large heart and a systolic murmur at the apex. The popliteal vessels were closed. The blood pressure was 130 systolic and 80 diastolic. The diagnosis was arteriosclerotic narrowing of the arteries of the lower extremities.

After two weeks in bed the patient contracted an infection of the left foot and lymphangitis of the left leg. The next day attacks characterized by loss of consciousness, feeble pulse and temporary cessation of respiration developed. Eight days later he died in one such attack. An electrocardiogram, revealing depression of the ST interval in leads 1 and 4, elevation in lead 3 and diphasic T waves in lead 4, was interpreted as suggesting acute myocardial infarction. Postmortem examination revealed massive pulmonary embolization involving the pulmonary conus and the main branches of the pulmonary artery; subacute myomalacia of the septum and left ventricle, and severe arteriosclerotic narrowing of the main branches of the left coronary artery, but no occlusion.

CASE 2.—*Calcific aortic stenosis* (service of Dr. George Baehr).

A man aged 68 had a history of mild diabetes and excessive alcoholism. For one year he had suffered from weakness, dyspnea and substernal and precordial pain on exertion. Eight days before his admission to the hospital, very severe and persistent cardiac pain developed, accompanied by intense dyspnea and prostration. An electrocardiogram, taken five months before admission, disclosed a prolonged PR interval (0.28 second) and intraventricular block. His blood pressure at that time was 170 systolic and 90 diastolic.

Examination in the hospital revealed slight cyanosis, congestion of the base of the lungs, enlargement of the heart and a harsh diffuse systolic murmur, loudest over the aortic area. The blood pressure was 90 systolic and 65 diastolic. The clinical diagnosis was coronary artery thrombosis and diabetes mellitus. The patient died twelve hours after admission.

Necropsy showed diffuse myocardial necrosis, especially in the subendocardium of the left ventricle and in the posterior papillary muscle, calcific stenosis of the aortic valve, carcinoma of the fundus of the stomach, and cirrhosis of the liver. The coronary vessels were moderately arteriosclerotic but widely patent.

CASE 3.—*Severe coronary narrowing without recent occlusion* (service of Dr. George Baehr).

A woman aged 42 had suffered from dyspnea and angina pectoris on effort and from intermittent claudication for five years. Six months before admission to the hospital she had a severe attack of cardiac pain, which recurred intermittently for seven weeks. During three months in bed the patient became intensely dyspneic and orthopneic, and edema of the ankles developed. After a partial remission the symptoms became greatly intensified three days before admission. On examination the patient was acutely dyspneic, orthopneic and somewhat cyanotic. The heart was enlarged to the left and its sounds were of poor quality. There was a gallop rhythm with a rate of 120 a minute. There were a large tender liver, dependent edema, pleural effusions and engorgement of the cervical veins. The blood pressure was 110 systolic and 55 diastolic but rapidly fell to 80 systolic and 60 diastolic. The electrocardiogram, taken a day after admission, disclosed a ventricular tachycardia with a rate of 200 a minute, right axis deviation, widening and notching of the QRS complexes and inversion of the T wave in lead 3. The patient died thirty-six hours after admission. The clinical diagnosis was coronary sclerosis, recent coronary thrombosis and congestive heart failure.

Postmortem examination revealed moderate arteriosclerotic narrowing of the left and severe narrowing of the right coronary artery and branches. There was an old atherosclerotic occlusion of the main right coronary artery, a large scar of a healed infarct with early aneurysm of the anterior wall of the left ventricle and acute myomalacia of the interventricular septum. Recent coronary occlusion could not be found.

COMMENT

The myocardial lesions in these cases were interpreted as being due to an intense myocardial ischemia caused by an inadequate coronary blood supply. Clinically and pathologically these cases did not appear to differ essentially from those presenting myocardial infarction due to an acute thrombotic occlusion of the coronary vessels. In most instances, coronary insufficiency was due in part to atherosclerotic narrowing of the coronary arteries. However, these changes did not usually appear sufficient in themselves to produce the acute myocardial necrosis, and in some cases myocardial infarction occurred when the coronary vessels were normal. It is likely that the associated disease, such as pulmonary embolism and calcific aortic stenosis, acted as a precipitating or contributing factor in the myocardial infarction. Occasionally two of these diseases were combined in one case. That these associated diseases were not merely coincidental appears to be corroborated by their frequency in cases of myocardial infarction without coronary thrombosis. Further support may be found in the pathologic physiology and clinical signs of these diseases, which indicate that there is a relative diminution in coronary flow and myocardial ischemia. Myocardial necrosis without coronary occlusion in the epileptic has been ascribed to spasm of the coronary arteries.[21] The possible role of coronary

21. Neubürger, Karl: Ueber die Herzmuskelveränderungen bei Epileptikern, Frankfurt. Ztschr. f. Path. 46: 14, 1933.

spasm in the production of myocardial infarction in the cases here reported is a matter of conjecture.

The relation of recurrent pulmonary embolism to myocardial infarction is discussed in detail elsewhere. We believe that coronary insufficiency occurs with pulmonary embolism chiefly because of the attendant shock. The associated asphyxia and exaggerated vagal reflexes causing coronary constriction may also play a role. Myocardial necrosis is not an invariable result of pulmonary embolism. Pulmonary embolism is most likely to produce myocardial ischemia severe enough to cause morphologic myocardial change if there is recurrent embolization, if the coronary arteries are already narrowed by arteriosclerosis, if the heart is previously hypertrophied and if there is an adequate duration of life after the embolism.

Clinical evidences of myocardial ischemia in calcific aortic stenosis are quite familiar. They consist essentially of angina of effort, conduction disturbances, abnormalities of the RS-T transitions and T waves in the electrocardiogram, and sudden death. The conspicuous hypertrophy of the hearts, the average weight of which in our series was 710 Gm., indicates the increased demand for blood in these cases. Presumably there is a chronic state of myocardial ischemia due to an inadequate coronary supply even when the coronary vessels themselves are normal. But frequently in these cases there was, in addition, moderate or severe narrowing of the coronary vessels, which tended to increase the coronary insufficiency. Coronary insufficiency in cases of calcific aortic stenosis is due, on the one hand, to the greater blood supply needed to accommodate the increased musculature and work of the heart and, on the other hand, to the diminished coronary flow because of the high intraventricular tension and increased systolic peripheral coronary resistance.[22] The coronary flow is further diminished when the vessels are narrowed by arteriosclerosis. This disproportion between coronary flow and myocardial requirement is accentuated during exertion because of the absence of ventricular reserve.

The pathologic physiology of coronary insufficiency in the remaining groups of cases can only be conjectured. In the cases occurring after operation, the shock of operation itself may have been an important factor; but it should be emphasized that in three of our four cases in this group the patients had hypertension and diabetes with large hearts, narrow coronaries and clinical and pathologic evidence of a previous coronary occlusion. The shock factor may be invoked also in cases of myocardial infarction associated with severe gastrointestinal hemorrhage and with embolism of the superior mesenteric artery. In cases presenting severe anemia, myocardial infarction might have resulted from the reduced oxygen-carrying power of the blood. Anemia per se was an extremely uncommon cause of myocardial infarction in our material. A systematic study of the relation of myocardial infarction to anemia will be reported.

The relationship between cerebral complications, particularly cerebral thrombosis, and myocardial infarction is also uncertain. The three patients in this group all had severe (so-called malignant) hypertension and large hearts, but their coronary vessels were surprisingly little altered. Myocardial changes in cases of malignant hypertension have been reported by Schürmann and MacMahon.[23] We believe that these lesions are the result of functional coronary insufficiency and not of the altered permeability of the coronary vessels, which these authors have termed "dysorie."

The remaining group of cases, in which acute myocardial infarction occurred as a result of coronary narrowing alone, is of special interest. Apparently such narrowing, if severe enough, can produce extreme myocardial ischemia and consequent acute infarction in the absence of acute occlusion. Usually a previous occlusion, arteriosclerotic or thrombotic, of a main coronary branch had already seriously compromised the coronary blood supply, while a large aneurysmal scar of the healed infarct had reduced the effective cardiac musculature. These incidents were denoted clinically not only by angina pectoris of effort but also by signs of congestive heart failure. Progressive narrowing of the remaining, already narrowed, coronary vessels finally produced sufficient ischemia to cause acute morphologic changes. The immediate precipitating factor is uncertain, but the occurrence of the acute infarction is usually denoted clinically by an intensification of the signs of failure with or without cardiac pain.

Finally, it should be reemphasized that the clinical features and electrocardiographic alterations attributed to acute coronary thrombosis are due actually to the resulting myocardial damage. Since acute myocardial necrosis may occur with severe coronary insufficiency without thrombosis, it is clear that in such a disease as calcific aortic stenosis and other conditions associated with coronary insufficiency, a clinical picture identical with that of coronary thrombosis may be observed and no coronary thrombus found. It would appear more accurate to employ the clinical diagnosis myocardial infarction than coronary thrombosis. An attempt should be made to determine clinically the presence of a contributing cardiac or extracardiac factor which may be responsible for the infarct.

SUMMARY

1. Thirty-seven cases of acute myocardial infarction not due to coronary thrombosis were observed in some 2,000 autopsies. In the last 1,000 autopsies 31 per cent of the cases of myocardial infarction were found without recent coronary thrombosis.

2. Twelve cases were associated with pulmonary embolism, eight with calcific aortic stenosis and six with intense coronary narrowing and old occlusion; four occurred after operation and three after a cerebral accident in patients with malignant hypertension. In three there was severe anemia and in one an occlusion of the superior mesenteric artery.

3. It is suggested that the acute myocardial damage in the various cases was due to intense coronary insufficiency. This insufficiency was due in part to arteriosclerotic narrowing of the coronary arteries and to myocardial hypertrophy but also to the abnormal circulatory dynamics of the associated disease, which usually precipitated the infarction. Myocardial infarction may also be due solely to progressive coronary narrowing of extreme degree.

4. Sudden death in aortic stenosis and other diseases associated with coronary insufficiency may be caused by severe myocardial ischemia and necrosis without recent occlusion of the coronary artery.

REMOVAL OF THE THYMUS

SURGICAL VERSUS ROENTGEN RAY EXTIRPATION

E. I. HASHIMOTO, M.D.
AND
C. B. FREUDENBERGER, PH.D., M.D.
SALT LAKE CITY

In a series of recent articles, co-authors Shay, Gershon-Cohen, Fels and the Meranzes [1] have reported that roentgen ray destruction of the thymus gland in young albino rats produced a delayed development of the male testes, with resultant temporary sterility, and a hypophysial change similar histologically to that produced by castration. These changes were said to be progressive to the age of 100 days, after which reparative processes were said to be instituted which resulted in complete recovery of the testes. These observations deserve careful consideration in the light of the many negative results previously obtained by surgical extirpation of the thymus. We believe that the average clinician should be aware of the differences in effect of the two methods. It is with this fact in mind that we wish to present our experimental results and views on this controversial subject.

We would assume that roentgen ray ablation of the thymus gland, experimentally at least, was for the same primary purpose as surgical removal, namely to determine what effects a lack of thymus secretion would have on the experimental animal. We would further assume that similar results should be obtained under the two circumstances.

Park and McClure,[2] who reviewed the entire subject of thymectomy and who included a series of experimental observations on dogs, were of the opinion that extirpation of the thymus probably does not influence growth or development and the thymus is not essential to life. Hammar,[3] Crotti,[4] Marine [5] and Andersen [6] have likewise reviewed the literature and have arrived at essentially the same conclusions. Our own observations, which we wish to present, add only to the confirmation of their data.

Pappenheimer [7] showed that complete removal of the thymus gland in the rat could be effected through surgical means. He made serial sections through the viscera of the neck and thorax to prove that there were no remnants postoperatively. Einhorn and Rowntree [8] believe that surgical removal is more satisfactory than roentgen irradiation. We wish at the outset to concur with them and with others who have performed thymectomy on the albino rat in the observation that thymectomy through the midline, sternum-splitting incision described by Basch [9] is a simple and complete operation. It required no longer than five minutes to anesthetize the animal, expose and remove the gland and repair the wound. Subsequent autopsy did not show regeneration of fragments. Thus the removal of the thymus could be said to be complete and final. Furthermore, it did not entail subjecting the animals to the repeated trauma which would result from the relatively massive doses of roentgen rays on four successive days, as in the procedure of Shay and his co-authors.[1] Yet these writers suggest that total destruction of the thymus is more easily and completely effected by roentgen irradiation. They insist that irradiation resulted in complete atrophy of the thymus and at the same time state that complete removal was not necessary to obtain the results which they report.

EXPERIMENTAL OBSERVATIONS AND RESULTS

Our observations were made on twenty-four male Wistar albino rats; twelve were thymectomized at an average age of 25 days, and twelve, used as controls, were subjected to the identical operative technic except for the actual removal of the gland. The rats were killed and examined post mortem at an average age of 90 days. The hypophysis, thyroid, adrenals, testes, epididymides and spleen were removed and weighed. Supplementary recordings as to body weight, head weight, body length and tail length were also made. These measurements were subjected to small sample statistical analysis in order to observe more accurately whether or not mathematically significant changes had occurred. All methods employed were standardized ones, previously used and described.[10]

*A Comparison of Mean Weights and Differences in Thymectomized and Control Male Wistar Albino Rats**

(From 25 to 90 day animals)

	Control	Tests	Difference
Body weight	267.00	265.30	—1.70
Head weight	21.46	21.65	+0.19
Body length	22.05	21.87	—0.18
Tail length	20.16	19.83	—0.33
Hypophysis	0.0083	0.0078	—0.0005
Thyroid	0.0180	0.0182	+0.0002
Adrenals	0.0278	0.0285	+0.0007
Spleen	0.5613	0.4917	—0.0696
Testes	2.8708	2.8178	—0.0530
Epididymides	0.7853	0.7609	—0.0244

* Measurements in grams or centimeters.

As a result of this experiment, we were unable to confirm any of the observations reported by Shay and his co-workers.[1] There were no significant quantitative changes in the length of the body and tail or in the weight of the head, body, hypophysis, thyroid, suprarenal glands, testes and epididymides. Weekly recordings of the body weight did not reveal significant changes. There was a significant change in the weight of the spleen, but we wish to reserve this fact for

future confirmation with another group of animals, which we are at present studying.[10a]

Criticism might arise from the fact that our rats were 25 days of age at the time of operative removal of the thymus, but Andersen,[6] whose work is not quoted by Shay,[1] with a more nearly comparable group of young male rats did not confirm their results. She reported that in animals thymectomized at the age of 1 day, for which litter mates served as controls, there were no significant alterations in the age or weight at puberty. She summarized her results by stating that "from an analysis of this work on thymectomy, we may conclude that thymectomy does not prevent, hasten or delay the arrival of sexual maturity, and it does not prevent the occurrence of normal litters. In other words, aside from the immediate effects of the operative injury, it has not been shown that deprivation of thymus, even in early life, has any effect upon the development and function of the sexual apparatus."

In reviewing the articles submitted by Shay and his co-workers [1] we were somewhat at a loss as to the exact number of litter mates used in their experiment. It was stated [1b] that there were thirty-five litters of animals, but there was no record in any of the articles of individual protocols to which reference could be made. The growth chart appears to have been constructed from one litter of animals (litter 19). Likewise, the organ weight: body weight ratios appear to have been derived from observations made on one litter (litter 18). In similarly limited data, it is always possible to obtain great variation in either direction, depending on the litter selected. Since their three papers, which followed in rapid succession, were admittedly incomplete, we have no doubt that future papers will contain the necessary data.

COMMENT

In view of the marked discrepancies in the results obtained with the two methods, i. e. surgical extirpation and roentgen ray ablation of the thymus, some explanation would seem logical.

The male albino rat at the age of 48 hours has an average length of from 47 to 52 mm.[11] The aperture of from 8 to 10 mm. through which Shay and his co-workers [1] irradiated the thymus would therefore constitute approximately one fifth of the total body length of the animal. This would seem to be a relatively large area to subject to massive roentgen ray exposure, although these authors [1b] went to some lengths to prevent stray irradiation.

Dissection of 2 day old animals reveals that in many instances the two superior poles of the thymus gland extend paratracheally as high as the thyroid gland. Further, there is hardly a difference of from 5 to 7 mm. between the upper portion of the body of the thymus and the lower portion of the thyroid. Conceivably, in order to effect complete exposure of the thymus gland, one must direct the roentgen rays dangerously close to the area of the thyroid; in fact it is questionable whether one could be absolutely certain that the thyroid gland did not receive stray irradiation. In further substantiation of these anatomic hypotheses, these authors say: "In some animals we tried to give exposures above the area of the thymus. This was found to be impossible, because in order to avoid the region of the thyroid the upper part of the thymus was usually involved, so that varying degrees of destruction of the thymus resulted in this group." Obviously, if it was impossible to avoid the upper part of the thymus during irradiation of the area near the thyroid gland, we must assume, conversely, that it would also be impossible to avoid the thyroid gland or immediately adjacent areas in attempting to destroy the thymus completely.

In strapping the animal to the board, the head is necessarily extended, throwing the base of the sphenoid bone, on which rests the pituitary gland, nearly to the level of the upper reaches of the superior poles of the thyroid gland. It would seem then that difficulty would be encountered in shielding not only the thyroid gland but also the hypophysis itself from the large doses of roentgen rays to which the thymus was subjected.

We mention these facts only because it has long been known [12] that extirpation of the thyroid gland gives rise to changes in the hypophysis which to us seem strangely similar to those described by Shay as the "physiologic castration" due to destruction of the thymus by roentgen rays.

Let us compare these descriptions. Shay [1b] said: "The pituitary gland seems slightly enlarged, more in the male than in the female. And the anterior lobe is the part most involved. There is an increase in the number of basophils. They are enlarged and show irregularities in staining affinity. So-called castrate cells make their appearance. . . . Eosinophils seem normal, although possibly slightly decreased in number." On the other hand, from experiments on an entirely different organ (thyroid), Severinghaus, Smelser and Clark,[13] in reviewing work by Simpson and Hunter,[14] Marine,[15] Trautmann,[16] Bryant [17] and Kojima [12] and also their own observations on pituitary changes resulting from removal of the thyroid gland, reported as follows: "Marked changes occur in the anterior lobe of the pituitary. The basophils are increased in number, are of maximum size, and give the pituitary the castrate appearance. Many have deeply chromatic elongated nuclei. Large numbers of typical castration cells are present." Certainly one might be justified in suspecting from these descriptions alone that the pituitary changes reported by Shay [1] might be in part due to unsuspected injury of the thyroid gland by the roentgen rays.

Furthermore, although in the literature available to us we were unable to find reports on the effects of removal of the thyroid gland at the early age at whcih the thymus experiment was undertaken, clinically it has often been demonstrated in cretins that there is a delay in growth of the sexual glands and accessories as well as in sexual maturation. With these observations in mind, the possibility cannot be excluded that effects other than those directly attributable to irradiation of the thymus gland might have contributed to the results reported by Shay and his co-workers.

10a. Since this article was submitted for publication on Feb. 8, 1939, additional data have been obtained making a total of twenty-four test animals with a similar number of controls. The results confirm the observations recorded.

SUMMARY AND CONCLUSIONS

Observations made on the effects of removal of the thymus gland from twelve male Wistar albino rats at the age of 25 days, and statistically compared with those on a similar group of controls, showed at 90 days that there were no mathematically significant changes in the length of the body and tail or in the weight of the body, head, hypophysis, adrenals, thyroid, testes and epididymides. The weekly increase in weight was not significantly altered. Microscopic sections of the testes of thymectomized animals showed no departure from the normal. Thymectomized animals between puberty and the age of 90 days were found to be capable of inseminating normal female animals.

Descriptions of the effects of ablation of the thymus by means of roentgen rays, as recorded by Shay and his co-authors, cannot be harmonized with the many reports of experimenters who surgically removed the gland. A partial review of the literature would suggest that the changes obtained by those employing roentgen rays might be due to injury to the thyroid gland.

TEMPORARILY POSITIVE KAHN AND WASSERMANN REACTIONS

IN INFECTIOUS MONONUCLEOSIS: REPORT OF A CASE

JOSEPH F. SADUSK JR., M.D.

NEW HAVEN, CONN.

The fact that temporarily positive serologic tests for syphilis may occur in infectious mononucleosis without evidence of syphilis has been noted but is not generally recognized. Apparently the earliest notation of this finding was made in 1928 by Löhe and Rosenfeld,[1] who described what they termed "monozytenangina" in a housewife aged 40. In the light of present knowledge this case would seem quite compatible with the angiose variety of infectious mononucleosis. It was Weber,[2] however, who in 1930 first called attention to the fact that temporarily positive serologic tests for syphilis may occur in glandular fever. He reported three cases which all yielded transiently positive serologic reactions as evidenced by positive Wassermann or Meinicke tests. A year later Gooding[3] described a series of twenty-seven cases (from the London epidemic of 1930) in which sixteen cases gave either a positive or an "incompletely" positive Wassermann reaction. Those cases which showed a negative Wassermann reaction were said in most instances to have yielded a positive Kahn reaction.

Radford and Rolleston[4] have also reported two cases of glandular fever with positive Wassermann reactions, but syphilis does not seem to have been adequately excluded.

Bernstein[5] in 1934 noted in two instances the association of a false positive Wassermann reaction with increased heterophile antibody titer, though the Eagle[6] flocculation tests were negative. In both patients the serums subsequently yielded negative Wassermann reactions on the twenty-fourth and fifty-eight day of disease respectively.

During the current year Hatz[7] has reported a case of infectious mononucleosis with a transiently false positive Wassermann reaction, a negative Kline reaction and a sheep cell titer for heterophile antibodies not rising above 1:32.

Out of sixty cases of infectious mononucleosis observed at the Johns Hopkins Hospital during the past five years, Bernstein[8] has recently collected six cases (including two cases previously reported) with temporarily false positive serologic reactions for syphilis. Of the sixty patients, thirty-seven had been given routine Eagle or Wassermann tests, the remainder not having been given serologic tests for syphilis.

In view of the clinical significance of these data it has seemed worth while to report the following case:

REPORT OF CASE

A student nurse, aged 23, admitted to the New Haven Hospital Jan. 10, 1938, complained of a cutaneous eruption.

Dec. 29, 1937, she had reported to the Nurses' Infirmary with an infection of the upper respiratory tract lasting two days. At that time she had complained of sore throat, swollen eyes, nasal discharge and slight general malaise. Elevation of temperature was minimal, reaching only 100 F. on the first day and falling to normal on the second day. January 9 the patient noticed a cutaneous eruption in the right antecubital fossa which, by the morning of January 10, had spread considerably. There were no other symptoms and she felt quite well. There was no history of syphilis and no reason to suspect that an acquired or congenital syphilitic infection existed.

On admission to the New Haven Hospital January 10 there was observed a rather faint morbilliform eruption over the neck, chest, abdomen, upper part of the back and in the right antecubital fossa. The anterior cervical nodes were enlarged and in both posterior cervical chains enlarged nontender nodes could be readily palpated, the enlargement being greater on the right than on the left. The temperature was 99.8 F. and the patient seemed quite comfortable and did not appear ill. The spleen was not palpable.

On admission the leukocyte count was 6,050 with 65 per cent lymphocytes. Among these were found a number of large cells, characteristic of those ordinarily present in infectious mononucleosis. The sheep cell agglutination test was positive in a dilution of 1:512. The Kahn reaction was 4+ and the Wassermann reaction was negative with the alcoholic antigen but 4+ with the cholesterinized antigen.

The patient's subsequent clinical course was quite satisfactory. She never felt particularly ill and she remained afebrile. The cutaneous eruption totally disappeared within twenty-four hours. The course of the sheep cell agglutination titer, the Kahn and Wassermann reactions and the blood counts are summarized in the accompanying table.

The enlargement of most of the cervical lymph nodes disappeared within a week after admission to the hospital, but several nodes could be palpated in the right posterior chain as late as February 5, and on March 5 a single node in the same chain was still palpable. February 5 a slight papular eruption over the forehead developed but subsided by March 5.

Agglutinations for various bacteria were done on the serum of February 5. There was no agglutination with the following antigens: Eberthella typhi, Salmonella paratyphi, Salmonella schottmülleri, Eberthella paradysenteriae (Flexner), Eberthella dysenteriae.

8. Bernstein, Alan: False Positive Wassermann Reactions in Infectious Mononucleosis, Am. J. M. Sc. **196**: 79 (July) 1938.

On admission the case was first regarded as one of German measles in that the cutaneous eruption, enlargement of the posterior cervical nodes and leukopenia seemed compatible with this diagnosis. But the presence of sheep cell agglutinins in high titer, the blood picture of January 10 and the fact that eruptions similar to this type are known to occur in infectious mononucleosis [9] all pointed to the latter diagnosis rather than to that of German measles.

It is important to note that without the proper blood studies one would have seriously considered secondary syphilis in this case and might have begun immediate intravenous antisyphilitic therapy.

COMMENT

There are several unusual features in this case, namely the high and persistent titer for heterophile antibodies, the atypical clinical picture of infectious mononucleosis simulating German measles and the relatively long duration of the false positive Kahn and Wassermann reactions.

A titer of 1:4,096 for heterophile antibodies is higher than one ordinarily finds in infectious mononucleosis, and whether or not there is any relation between this and false positive Wassermann reactions is not clear. Bernstein [8] has observed a sheep cell titer of 1:33,000 in a patient whose serologic reaction was negative while on the other hand in one of his cases presenting both positive Eagle and Wassermann reactions the sheep cell titer was only 1:64. In addition, the heterophile antibodies in Hatz's case [7] never rose above a titer of 1:32.

Apparently, false positive serologic reactions for syphilis may appear in infectious mononucleosis as early as the first week of disease. They usually revert to negative some time during the third to the seventh week, though in the present case they did not become negative until the tenth week. The heterophile antibodies still persisted in high dilution even at this time, thus failing to show a parallelism with the course of the Wassermann reaction.

There has been no adequate explanation advanced for the cause or nature of the false positive reactions, and it is a phenomenon which deserves further investigation in view of the fact that one is dealing with a disease of unknown etiology. Partial removal of heterophile antibodies has no effect on the tests for syphilis, nor do the sheep cell titers necessarily parallel these tests.

It is also unknown whether cases of infectious mononucleosis with falsely positive Wassermann reactions fall into a special group, or, if not, how frequently they occur in the general run of infectious mononucleosis. In Gooding's group of cases from the London epidemic of 1930 the incidence was over 60 per cent. In Bernstein's series [8] of sporadic cases the incidence of transiently positive Wassermann reactions was 16 per cent.

During the past seventeen years at the New Haven Hospital there have been observed forty-six admissions in which the diagnosis of infectious mononucleosis has been made. In thirty-seven of these cases either Kahn or Wassermann tests were done, with the result that three of these, including the present case, yielded positive results. Of the other two patients the first was a girl aged 8 years who was admitted on the eleventh day of disease. At that time the Wassermann reaction was negative with the alcoholic antigen but 1 plus with the cholesterinized antigen. The second patient was a college student aged 20, admitted on the seventeenth day of illness. He had as a complication a severe Vincent's stomatitis. On the day of admission the Kahn reaction was 2+, the Wassermann reaction was negative with both the alcoholic and the cholesterinized antigen, and the sheep cell agglutination titer was 1:128. Unfortunately there is no record of serologic tests having been repeated in either of these first two cases. It seems reasonable to suppose, however, that in both instances the mechanism of the positive tests may have been similar to that observed in the third case, since no history of syphilis was obtained in either case and no congenital stigmas were present. If one considers that these three cases are similar, the present incidence of transiently (?) positive tests for syphilis in the series of cases at the New Haven Hospital is approximately 8 per cent, as contrasted with Bernstein's incidence of 16 per cent and Gooding's incidence of over 60 per cent. It should be emphasized, however, first that routine Wassermann tests were not done in our whole series; secondly, that serologic tests for syphilis were not repeatedly carried out, and, thirdly, that Kahn tests were usually done on admission during the very early stages of the disease. It seems possible, therefore, that more patients with positive reactions for syphilis might have been observed if blood tests had been repeated during the subsequent course of the illnesses described.

Blood Counts, Sheep Cell Agglutinations, Kahn and Wassermann Reactions

Capsule Formation and Virulence.—A characteristic of certain species and strains of bacteria which may well be regarded in some cases as a manifestation of adaptation to parasitic existence, as probably was first suggested by Babes, consists in the formation of a capsule. This structure in such organisms as the various types of pneumococci and Friedländer bacilli appears to be composed of various kinds of complex carbohydrate gums. That produced by the anthrax bacilli is described by Tomcsik as a protein or protein-like substance. It extends about the somatic portion of the bacterium and can be sharply differentiated from this vegetative body by suitable staining procedures. The experiments of Danysz were among the first to indicate a definite relationship between the formation of a capsule and virulence in pathogenic bacteria, and many subsequent studies have in the main served to establish this structure as being of great significance in permitting the survival of the bacterium in vivo. Its presence, nevertheless, cannot be taken as an infallible sign of an organism's capacity to cause disease, since a number of harmless encapsulated saprophytes are known.—Zinsser, Hans; Enders, John F., and Fothergill, LeRoy D.: Immunity Principles and Application in Medicine and Public Health, New York, Macmillan Company, 1939.

VERTEBRAL FRACTURES PRODUCED BY METRAZOL-INDUCED CONVULSIONS

IN THE TREATMENT OF PSYCHIATRIC DISORDERS

PHILLIP POLATIN, M.D.
MURRAY M. FRIEDMAN, M.D.
MEYER M. HARRIS, M.D.
AND
WILLIAM A. HORWITZ, M.D.
NEW YORK

Convulsions induced by metrazol have been widely applied in the past few years in the treatment of mental disorders. At first limited to the treatment of schizophrenia, this therapy is now being employed for the affective disorders [1] and also for severe psychoneuroses.[2] Von Meduna [3] in one of his early papers stated that, although the treatment was quite drastic, no inherent danger was involved. Occasional fractures of the long bones and dislocations have been reported.[4] Recently

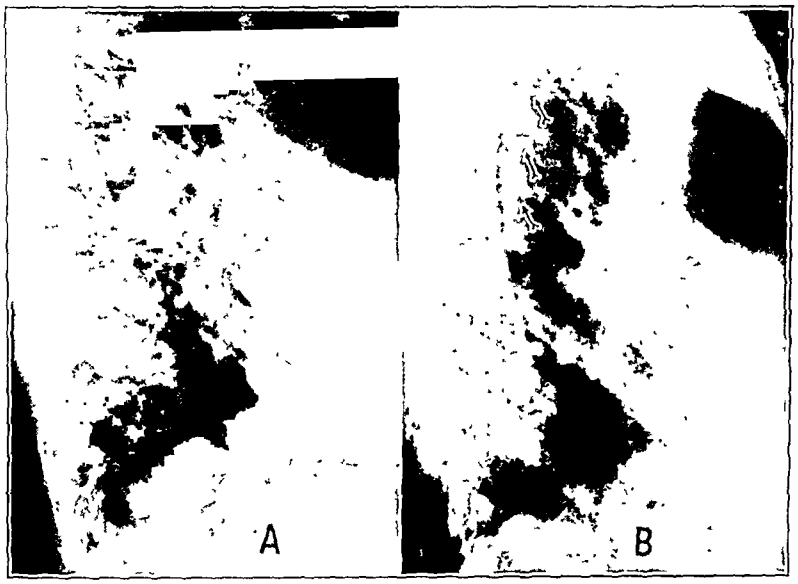

Fig. 1 (case 31).—*A*, taken before the convulsion, reveals no abnormalities, *B*, taken after the convulsion reveals compression fractures of the fourth and sixth thoracic vertebrae and possible injury to the fifth.

von Meduna and Friedman [5] compiled statistics from various sources with regard to the "mechanical" complications, which include dislocations and fractures of the extremities. They did not include the numerous temporomandibular dislocations which undoubtedly occur but which are reduced without difficulty or sequelae. They reported an incidence of 1.1 per cent of such "mechanical" complications. A survey of the literature discloses no reference to vertebral injuries as the result of metrazol therapy except the recent report by Wespi [6] of a case of fracture of the seventh thoracic vertebra. It is our purpose to report a series of cases of treatment with metrazol in which compression fractures of the thoracic vertebrae were found in a very large percentage after the convulsions.

Attention was attracted to the spine when several patients complained of more or less severe backache, localized chiefly to the midthoracic region, after the convulsions. X-ray examination of the spine disclosed compression fractures of the bodies of the vertebrae. Therefore all available patients who had received metrazol therapy, whether they had complained of backache or not, were examined by means of roentgenograms. Recently, in order to eliminate the possibility that the fracture may have existed prior to treatment, we have in several instances examined the spine before treatment and found it normal, whereas after the convulsions fractures were demonstrated by roentgenograms.

Convulsions induced by metrazol were utilized in the treatment of fifty-eight psychiatric patients, twenty-three males and thirty-five females. Of these, fifty-one (twenty males and thirty-one females) were available for examination. The youngest patient treated was 15 and the oldest 50, the average age for the entire group being 28.7 years. Fractures were found in a total of twenty-two (43.1 per cent) of the patients examined, of whom six were males (30 per cent) and sixteen females (51.6 per cent). The fractures were all found in the thoracic vertebrae and were most common in the midthoracic region. The number of segments affected varied from one to eight and averaged between three and four. Table 1 lists in detail the observations in the fifty-eight cases and includes the mental diagnoses and the number of metrazol convulsions. Table 2 summarizes the results of the x-ray examinations.

REPORT OF CASES

CASE 31.—C. G., a white woman aged 28, single, admitted to the Psychiatric Institute Dec. 16, 1938, with a manic-depressive psychosis, depressed type, of three months' duration, was well nourished, of asthenic habitus and normal on physical and laboratory examination. Roentgenograms of the thoracic part of the spine Jan. 10, 1939, showed no bone or joint abnormalities. January 11 the injection of 3 cc. of 10 per cent solution of metrazol, followed fifteen minutes later by 4 cc., produced only petit mal attacks. January 13 the injection of 5 cc. followed fifteen minutes later by another 5 cc. produced only petit mal attacks. January 15, 6 cc. elicited only a petit mal attack. January 18, 7 cc. produced a generalized convulsion resembling an epileptiform attack. Later that day the patient complained of moderate pain in the midthoracic region of the back. Stereoscopic x-ray films of the thoracic part of the spine taken the same day showed compression fractures of the bodies of the fourth and sixth thoracic vertebrae and suggestive but less convincing evidence of an injury to the fifth (fig. 1).

CASE 32.—G. L., a white woman aged 28, single, admitted to the Psychiatric Institute Nov. 16, 1938, with a manic-depressive psychosis, depressed type, of six months' duration, was well nourished, of pyknic habitus and normal on physical and laboratory examination. Roentgenograms of the thoracic and upper lumbar parts of the spine Jan. 10, 1939, revealed no bone or joint abnormalities. January 11 the injection of 4 cc. of a 10 per cent solution of metrazol produced a generalized

epileptoid convulsion, which was repeated January 13 with the same dose. Later that day the patient complained of moderate pain in the midthoracic region of the back. Stereoscopic x-ray films of the thoracic part of the spine taken the same day showed evidence of compression fractures of the fifth, sixth, seventh, eighth and ninth thoracic vertebrae.

COMMENT

The technic of administering metrazol to induce convulsions in these patients was only slightly modified from that described by Meduna,[3] in that a smaller initial dose (3 cc. or, rarely, 4 cc. of a 10 per cent solution) than the 5 cc. advocated by him was given intravenously. The majority of convulsions occurred with a dose of from 4 to 6 cc. Later in our treatment, if a convulsion was not produced another injection of 1 cc. more than the original amount was given in fifteen minutes. If this did not elicit a grand mal attack, treatment was discontinued for that day. A similar procedure was used on subsequent treatment days, the dose being increased 1 cc. until a convulsion was attained. Treatments were given twice or, more often, three times weekly. The maximum dose of metrazol used was 11.5 cc. We wish to emphasize that none of our patients received any injury from external causes, such as falling out of bed or striking the body against the wall or the headboards or footboards of the bed during a convulsion. The patients were under constant observation until they were fully conscious and in complete contact with their surroundings. This procedure is similar to that recently advocated by Meduna and Friedman.[5]

We have found that the pattern of the convulsion induced by metrazol is similar to that described by Finkelman, Steinberg and Liebert.[7] In general, from five to ten seconds after the intravenous injection of metrazol, convulsive movements began in the face, shoulders and arms; these were followed quickly by a rhythmic clonic phase. In about fifteen seconds a tonic phase ensued. The head was retracted and the body was held rigid. This phase lasted from five to thirty seconds and was followed by another clonic phase, during which the spine was repeatedly flexed. It is possible that the vertebral injuries occur during this phase of the convulsion.

* The letter T and the number represent a compression fracture of the corresponding thoracic vertebra.
† A roentgenogram taken prior to metrazol therapy revealed no fracture.

7. Finkelman, Isidore; Steinberg, D. L., and Liebert, Erich: Treatment of Schizophrenia with Metrazol by Production of Convulsions, J. A. M. A. **110**: 706-709 (March 5) 1938.

In our series there was no relationship between the total number of convulsions and the appearance of the fractures or the number of vertebrae affected. Several patients sustained fractures after one or two convulsions, while others showed no evidence of injury after eighteen or twenty-two seizures.

TABLE 2.—*Summary of Vertebral Fractures in Metrazol-Treated Patients*

	Male	Female	Total
No. of patients treated	23	35	58
No. of patients examined roentgenographically	20	31	51
No. of patients with vertebral fractures	6	16	22
Percentage of patients with vertebral fractures	30.0	51.6	43.1

In order to indicate that in all probability these fractures did not result as a consequence of any peculiarity in our technic or dosage, we wish to cite a case recently observed at this hospital but not included in our series. The patient had had two metrazol-induced convulsions at another institution. On his admission to the Psychiatric Institute, compression fractures of the seventh, eighth, ninth and tenth thoracic vertebrae were found on the roentgenograms.

Fig. 2 (case 26).—A white girl aged 18, with schizophrenia, had twenty one metrazol-induced convulsions. A roentgenogram then revealed compression fractures of the fourth, fifth, sixth, seventh and eighth thoracic vertebrae.

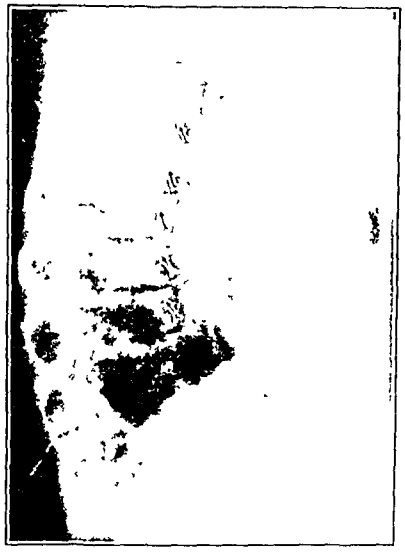

Fig. 3 (case 29).—A white woman aged 32, with schizophrenia, had ten metrazol-induced convulsions. A roentgenogram then revealed compression fractures of the fifth, sixth, seventh, eighth and ninth thoracic vertebrae.

Fig. 4 (case 19).—A white woman aged 33, with a manic depressive psychosis of the depressed type, had one metrazol induced convulsion. A roentgenogram then revealed compression fractures of the sixth, seventh and eighth thoracic vertebrae.

In general the degree of injury bore no relationship to the intensity of the subjective complaint of backache. Many patients who complained of pain in the back did not present any demonstrable vertebral fractures, whereas others with fractures, especially male patients, did not complain of pain. There did not appear to be any direct relationship between the occurrence of fracture and the habitus or age of the patient. All our patients were physically healthy and well nourished, stemming from the middle class of society, and showed no evidence of nutritional disturbance.

The most frequently affected segments were in the midthoracic region. In the roentgenograms, the appearance of the fractures varied. Fragmentation and compression of the anterior portion of the upper surface of the body was most common. In about half the cases the fractures manifested themselves only by a slight forward displacement of a disklike fragment of the upper portion of the body. Flattening in the vertical direction and wedge formation were often seen. In several instances the compression of the body was marked, resulting in a shortening of the vertical diameter to about one half its normal height. Moderate kyphosis and scoliosis were noted in a number of cases as a concomitant deformity.

The fractures of the bodies of the vertebrae were probably caused by the action of the muscles of the spine and trunk. The preponderance of fractures of the anterior portions of the vertebral bodies suggests that they are produced by sudden anterior flexion of the spine. Similar fractures after the spasms of tetanus have previously been reported.[8] Roberg[9] called attention to the bending force of the powerful spinal flexors and the relatively weak opposing extensors in producing compression fractures of the anterior portions of the midthoracic vertebrae in tetanus.

Although the complication of vertebral fracture is serious, our observations tend to agree with the published reports of the efficacy of metrazol therapy in the treatment of psychiatric disorders. To prevent this complication, we are investigating a method whereby the patient is placed on his side and acutely flexed, the metrazol being injected while he is in this position. It is hoped thereby to reduce the sudden flexions of the spine which may be the cause of the vertebral injuries. We have had too few patients treated in this new position to report regarding its effectiveness.

SUMMARY AND CONCLUSIONS

1. In fifty-one cases of psychiatric disorders in which metrazol was used to produce convulsions, x-ray examinations of the thoracic part of the spine were subsequently performed.

2. These examinations revealed compression fractures of the vertebrae in 43.1 per cent of the cases. The incidence was higher in female patients than in male patients.

3. In most instances the fractures were multiple.

8. Chasin, Adib. Ueber Veranderungen in der Wirbelsaule nach Tetanus, *Fortschr. a. d. Geb. d. Röntgenstrahlen* **46**: 427-441 (Oct.) 1932. Zukschwerdt, L., and Axtmann, R.: Wirbelveränderungen bei Wundstarrkrampf, Deutsche Ztschr. f. Chir. **238**: 627-634, 1933.

9. Roberg, O. T., Jr.: Spinal Deformity Following Tetanus and Its Relation to Juvenile Kyphosis, J. Bone & Joint Surg. **19**: 603-629 (July) 1937.

4. It is probable that these fractures are produced by acute anterior flexion of the spine, which occurs during the convulsion induced by metrazol.

5. In view of the beneficial effects of metrazol in the therapy of mental diseases, attempts are being made to avoid this complication.

Clinical Notes, Suggestions and New Instruments

PURPURA HAEMORRHAGICA FOLLOWING USE OF SEDORMID

TWO ATTACKS IN ONE PERSON

TERESA MCGOVERN, M.D., AND IRVING WRIGHT, M.D., NEW YORK

Cases of purpura haemorrhagica after the use of sedormid (allyl-isopropyl-acetyl-carbamide) have been reported with increasing frequency since 1933. Joekes [1] reviewed the literature on this subject and stated that there were to date thirty-seven reported cases of purpura haemorrhagica due to sedormid. Since the period covered by his recent survey, seven more cases have been added to the literature.[2] It is interesting to note that on March 5, 1938, the Council on Pharmacy and Chemistry of the American Medical Association [3] declared sedormid not acceptable for New and Nonofficial Remedies. Also of the twenty recorded observers, only four are Americans.[4] In view of this we feel that it might be pertinent to describe a recent case of severe purpura haemorrhagica with two separate episodes due to this sedative.

REPORT OF CASE

A white woman aged 57 complained of multiple subcutaneous hemorrhages, which she had noticed on finishing her housework that evening. No injury had been sustained to account for the condition. Her legs, thighs, arms, body and mouth had hundreds of hemorrhages ranging in size from petechial spots to areas 6 cm. in diameter. Many of these larger areas were raised from 2 to 3 mm. in height; none were painful when touched. The hemorrhages in the mucous membrane of the mouth were of two varieties, some being flat and others pedunculated. The heart and lungs were normal; the abdomen, liver and spleen were not palpable. A capillary fragility test [5] produced 100 petechial hemorrhages in five minutes, and the entire forearm and hand became hemorrhagic. The clinical impression was of aplastic anemia, scurvy or idiopathic purpura.

When she was hospitalized early the next morning the areas had increased in size, a large hematoma was present on one elbow and she was spitting blood. A vitamin C saturation test [6] gave a normal result, 625 mg. (of 1,000 mg. given intravenously) being excreted in five hours. X-ray studies of the extremities for evidence of subperiosteal hemorrhages gave negative results.

No new hemorrhages appeared after her entrance into the hospital, which was concomitant with the large dose of vitamin C. Since she had shown a general avitaminosis a year before and because she had a habit of taking sedatives for insomnia, the possibility suggested itself that the excretion of dietary vitamin C had been accelerated by some drug (acetylsalicylic acid, for one, has been reported to cause depletion of vitamin C reserves [7]). For this reason 1,000 mg. of crystalline vitamin C (cebione-Merck) was given in 10 cc. of water intravenously each day. No other medication was administered. Studies of the blood made almost daily are presented in the table.

Questioning about self-prescribed medicine brought the information that the patient had taken one-half tablet of sedormid nightly for several months, with no ill effects. After a lapse of about a month she took a whole tablet the night before the onset of purpura. She recalled that she soon became acutely ill, with chills, fever and excessive thirst. A sleepless night was followed by a raging headache the next morning. Feeling better later, she had been astonished on changing her clothes in the evening to find her skin spotted with hemorrhages.

After a week's hospitalization, when her blood platelets had started to increase and her hemorrhages to disappear, the patient was discharged. Because sedormid was suspected of being the cause of her illness, it was not readministered for fear of recurrence.

Two months later she again took one-half tablet of sedormid at bedtime. Within two hours chills and fever were experienced, and her stomach "felt as if it were stretching." The next day her mouth was filled with hemorrhages, so that she was spitting blood continuously. There was oozing from the nose, and scattered over her body were approximately 300 petechial hemorrhages. Several large ecchymotic areas, all less than 2.5 cm. in diameter, appeared over the elbows and thighs. Two days later more hemorrhages appeared on the extremities. She was ashen colored and appeared ill. As she now refused intravenous injections, oral doses of 1,000 mg. of vitamin C were given daily. It required three weeks for the areas to disappear. At the present time, one month after the recurrence, she has residual stiffness of her knees, which may have been caused by hemorrhage into the joints.

Studies of the Blood

Day of Illness	1st	3d	4th	6th	7th
Red blood cells (per cubic millimeter)	3,760,000	4,236,000	3,870,000	3,990,000	4,250,000
White blood cells (per cubic millimeter)	4,900	3,750	3,350	3,850	4,150
Platelets (per cubic millimeter)	90,000	84,000	52,000	110,000	140,000

Basophils	2	0	0	0	1
Monocytes	2.5	4	5	5	6
Small lymphocytes	29.5	52	42	54	48
Large lymphocytes	2	2	3	3	5

COMMENT

While it is probable that many persons have suffered no ill effects from sedormid, a study of forty-five cases of purpura haemorrhagica following its use should cause real concern. The different stages at which illness may appear are of interest. Of the persons in whom purpuric manifestations developed, the majority indicated an allergotoxic reaction, since they had taken it for some time with no untoward effects, only to show hemorrhages when they resumed it after varied lapses of time. In another group apparently an intolerance for it developed, purpura appearing after a period of continued use. A still smaller number of persons who are reported to have reacted to their first dose seemed to have an idiosyncrasy for this drug. In all cases there was a strikingly similar clinical picture, followed generally by complete recovery on withdrawal of sedormid. In one instance, however, a psychosis was reported to have followed the disappearance of visible symptoms, and in the reported case

there is residual stiffness of the knees. One is led to speculate, therefore, on the possibility of such serious manifestations as may result from lesions in the brain and other important areas.

CONCLUSION

Evidence accumulated by various authors over five years demonstrates that sedormid may cause a serious hemorrhagic syndrome. This emphasizes the need for further study of its properties, restriction of its sale except on a physician's prescription and caution on the part of the physician in recommending its use.

A SIGN OF ULNAR PALSY

ROBERT WARTENBERG, M.D., SAN FRANCISCO

It seems to me worth while to point out the diagnostic importance of a sign of ulnar palsy that is apparently little known and is not even mentioned, for example, in the leading textbooks of neurology or in monographs on the peripheral nerves. This sign consists of a position of abduction assumed by the little finger. For years I have been observing this sign and have found it to be present in many cases, regardless of the cause of the palsy.[1]

Sometimes the fourth finger too has a tendency to assume a position of abduction, but usually it is only the little finger that is found in an abnormal position. In many cases this abduction was nearly extreme and resembled a paralytic contracture. It was found to be most conspicuous when the patient was asked to extend his fingers at the proximal joints. The importance of this sign has become increasingly evident from numerous experiences which indicate that this tendency of the little finger to be abducted may constitute an early (in some cases the first) and also a late sign of ulnar palsy.

It is my definite impression that from this point of view the sign deserves special attention. To illustrate this, the case of an intelligent female patient who had a slowly developing ulnar palsy is cited. This patient reported that the first thing she had noticed in respect to her hand was a tendency of the little finger to deviate outward. In other cases this deviation outward of the little finger has been noticed together with the beginning of paresthesias in the fourth and fifth fingers.

To show the importance of this sign as a very late manifestation of ulnar palsy, another case may be cited—that of a physician who fourteen years ago suffered a severe traumatic right-sided ulnar palsy. In the course of time all the signs of this palsy (atrophies, paralyses, sensory changes) completely subsided. In this case the abducted position of the little finger is now the only remaining demonstrable sign of an ulnar palsy sustained fourteen years ago. Recently I saw a patient who had been operated on for late ulnar palsy successfully by Dr. H. C. Naffziger fourteen years ago. In this case the position of abduction of the little finger has been the outstanding clinical feature.

From the physiologic standpoint this sign is easily understandable. Adduction of the little finger is performed by the interosseous and abduction by the hypothenar muscles. Both groups of muscles are innervated by the ulnar nerve. However, in abduction of the little finger, the musculus extensor digiti minimi proprius and the branch to the little finger of the musculus extensor digitorum communis also play a definite part. These are both innervated by the nervus radialis. If the muscles innervated by the ulnar nerve are weak, those innervated by the intact nervus radialis predominate in strength and abduct the little finger. Thus it is understandable why this abduction of the little finger in ulnar palsy is best seen when the musculus extensor digitorum communis comes into action and extends the fingers and the hand. In cases of combined palsy of the nervus ulnaris and nervus radialis this sign would not be present. Normally the spreading of the fingers and abduction of the little finger is much more forcefully performed with the fingers extended than with the fingers flexed. In ulnar palsy this difference is much more pronounced in the little finger. This proves again the importance of the extensors of the little finger in the mechanism of its abduction.

From the Division of Neurology of the University of California Medical School.

1. Wartenberg, Robert: Kleine Hilfsmittel der neurologichen Diagnostik, Nervenarzt. 3: 594, 1930.

Borchardt[2] described a case of ulnar palsy in which he assumed that only the musculus abductor digiti quinti was preserved. Foerster cited this case as a proof that this muscle was innervated by the nervus medianus. Foerster[3] presented a photograph made in a case of disease of the nervus ulnaris in which there was marked abduction of the fifth finger. He stated that in this case all the muscles of the hand that normally are innervated by the nervus ulnaris were innervated by the nervus medianus, except for the musculus interosseus volaris tertius (adductor digiti quinti).

These two explanations of the phenomenon are based on the supposition that the median nerve in these cases innervated the muscles usually regarded as innervated by the nervus ulnaris. Aside from the fact that this must occur only exceptionally, such an explanation does not come into consideration in my cases, in which the picture was in every way typical and there was no other evidence of innervation by the nervus medianus as a substitute for the nervus ulnaris. There was typical involvement of all the muscles normally innervated by the nervus ulnaris.

In another case of abduction of the little finger in ulnar palsy Foerster[3] assumed that, after the ulnar nerve had been affected, all the muscles had been restored to normal except the musculus adductor digiti quinti. The isolated palsy of this muscle had thus led to an abducted position of the little finger. This explanation by Foerster seems to me a little far fetched, as it is not understandable how, after all of the other muscles controlled by the nervus ulnaris had been restored, one would remain affected for many years.

My explanation appears more simple and adequate. I assume that abduction of the little finger in ulnar palsy is due to the predominance of the musculus extensor digiti quinti and the branch of the musculus extensor digitorum communis to the little finger over the muscles innervated by the nervus ulnaris which adducts the finger. Thus it is not necessary to resort to the extraordinary supposition that in ulnar palsy only the adductor digiti quinti may be involved or fail to be restored, or that the abductor digiti quinti has been spared. My explanation is supported by the strong influence of the extensors of the fingers on their abduction in cases of slight ulnar palsy, the abduction of the little finger becoming more than usually enforced when the fingers are extended, i. e., when the extensors come into play.

With regard to the use of this sign in differential diagnosis, it is worth while mentioning that Hoff and Schilder[4] found, in cases of cerebellar disease and of beginning multiple sclerosis with cerebellar lesions, this same tendency of the little finger to abduction.

USE OF SERUM TELLURITE AGAR FOR THE ISOLATION OF PNEUMOCOCCI

ELIZABETH PETRAN, PH.D., BALTIMORE

Serum tellurite agar,[1] which is used as a routine in this laboratory for the examination of cultures taken from the throat and nose for Corynebacterium diphtheriae, has been found very satisfactory for the isolation of pneumococci.

On this medium practically all strains of pneumococci produce very characteristic colonies. The colonies, which vary in size from 0.1 to 1 mm. in diameter, are very thin and flat, entire and gray with a brownish gray center. Some give the appearance of having a raised edge and a depressed center. Recently isolated and virulent type III pneumococci produced large (from 3 to 4 mm.), raised, watery, mucoid, light gray colonies. While the morphologic appearance of the colonies of pneumococci on this medium is very much like that produced on ordinary blood

From the Bureau of Bacteriology, Maryland State Department of Health.

1. Dissolve 1.5 [illegible] agar in beef infusion broth. Adjust hydrogen [illegible] 7.2 and 7.4, bottle in convenient amounts [illegible] rilize in the autoclave at 15 pounds pressure for twenty minutes. Melt this base in the Arnold sterilizer when ready to use and cool to 50 C. Add 5 per cent sterile human or hog serum, 0.2 per cent of dextrose from a sterile solution (2 cc. of a 10 per cent dextrose solution to 100 cc. of base) and 0.01 per cent of potassium tellurite (1 cc. of a 1 per cent sterile solution). Pour into Petri dishes.

agar, the pneumococcus colonies are easily distinguished from those of streptococci. The colonies are not always typical, however, until the plates have been incubated for twenty-four hours.

In general, streptococci produce raised, black colonies on serum tellurite agar. Certain strains of hemolytic streptococci which produce large mucoid colonies are difficult to distinguish from the colonies of type III pneumococci. The mucoid streptococcus colonies are, however, darker than pneumococcus colonies and do not usually have an entire edge. The tellurite medium has the added advantage that proteus-like and spore-forming bacteria do not produce spreading colonies.

This method has been found to facilitate greatly the routine isolation of pneumococci from mixed cultures.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE. HOWARD A. CARTER, Secretary.

FEVER THERAPY BY PHYSICAL MEANS

FRANK H. KRUSEN, M.D.
AND
EARL C. ELKINS, M.D.
ROCHESTER, MINN.

During the past few years, interest in the production of fever by physical means has greatly increased. More than 600 articles have been written and published on the subject. Excellent research work has been done, and conservative scientific conclusions have been drawn. The value of fever therapy as an important therapeutic agent in the treatment of certain diseases has been definitely proved.

The treatment of more than fifty diseases by means of artificial fever therapy has been attempted. The results in the majority of these diseases were not encouraging, although with a selected few the method has given promise of great usefulness. It must be emphasized, however, that fever therapy is probably of little or no value in the treatment of many diseases concerning which its use has been studied, and in some diseases it may even become dangerous.

GENERAL PRINCIPLES

Numerous studies on the effects of fever produced by physical means indicate that these effects produce certain definite changes in the body.

Effects on Circulation.—The pulse and circulatory rates are increased by fever therapy, and both the volume output of the heart and the velocity of the blood may be increased by as much as 400 per cent. There is an initial increase which is followed by a decrease in the pulse pressure. There is a marked increase in the pulse volume in the fingers of the patient in all types of artificial fever with the exception of that caused by foreign proteins. It has been suggested that the vasodilatation which occurs during fever produced by foreign protein is possibly of central origin, whereas that which occurs in artificial fever induced by external heating, with consequent prevention of loss of heat, is chiefly of peripheral origin.

The maximal increase of circulation in artificial fever occurs, in general, at temperatures between 103 and 104 F. (39.4 and 40 C.). Alterations appearing in the electrocardiogram are not uniform. The electrocardiograms show disappearance of the normal sinus arrhythmia, and the cardiac rhythm becomes remarkably regular. The conduction time (PR interval) is shortened about 0.02 to 0.06 second during the elevation of bodily temperature, being shortest at 105 F. The conduction rate concomitantly slows to its former velocity as the temperature falls.

Studies made by means of sphygmograms, phlebograms and electrocardiograms of patients undergoing fever treatments indicate that the total filling time of the ventricle is rapidly reduced by the time the temperature is elevated to 100.5 F. and reaches its lowest figure at 103.5 F. After this, the filling time increases slightly, so that it again becomes greater than the emptying time.

The curves illustrating filling times suggest that both the distressing symptoms and the subjective discomfort often experienced by patients during the induction of artificial fever might be accounted for by an inadequate filling of the heart because of an insufficient duration of the filling time. Compensation may be accounted for by a more adequate ventricular filling brought about by an increase in the duration of the filling time.

There is little or no change in the volume of the blood and no change in the viscosity of the blood when the intake of fluids is encouraged during the fever sessions. Artificial fever unaccompanied by sweating does not of itself bring about any considerable change in the blood volume, but when fever is accompanied by profuse perspiration, the reduction in blood plasma may be so great as to produce peripheral vascular collapse.

Absorption of fluids from the intestinal tract may be retarded during high fever, but the intravenous administration of fluids permits rapid restoration of blood volume. The visible capillaries of the nail beds are increased in number and size. The erythrocyte count generally is not changed. There is an initial decrease in the number of leukocytes, with a subsequent increase. There is a leukocytosis which starts during the fever period and rises in tidelike fashion with the addition of waves of neutrophilic cells and then gradually recedes to prefebrile levels in from twenty to twenty-four hours. This leukocytosis is varied, the total cell count ranging from 10,000 to 60,000.

Prolonging the fever, especially at high temperatures, delays leukocytosis or at least produces a smaller increase in leukocytes than does a shorter or less intense session of fever. It has been shown that continuous high fever in the rabbit prevents leukocytosis and may eventually lead to leukopenia. This action is explained by a progressive fall in the lobe index (number of nuclear lobes per hundred polymorphonuclear leukocytes), indicating that the bone marrow is pouring cells into the blood but is unable to keep pace with the emigration of these cells to the tissues.

Sessions of fever produce nuclear changes in the polymorphonuclear leukocytes, and these changes are in part toxic and in part the result of accelerated metabolic activity. There is a tendency to hypersegmentation and to the production of macropolycytes.

Bone marrow which has been previously stimulated but which is not being actively depleted by demands made by the tissues will respond to artificially induced fever by marked leukocytosis. Conversely, bone marrow which is being stimulated actively but which is also being drained by demands of the tissues will respond with only slight leukocytosis. This is illustrated by the slight response to the malarial paroxysm which

From the Section on Physical Therapy, the Mayo Clinic.

occurs late in this disease. The same bone marrow, after a period of recuperation following quinine treatment, will respond by marked leukocytosis when subjected to artificial fever.

Histologic studies of organs of animals subjected to fever sessions continuously until death disclose focal accumulations of polymorphonuclear leukocytes which often reach the proportions of abscesses. In the lymph nodes there is early and progressive destruction of the lymphocytes followed by polymorphonuclear infiltration and later by a marked proliferation of actively phagocytic clasmatocytes. At this later stage, the nodes thus involved are hypoplastic without evidence of lymphocytic regeneration.

There is slight, if any, change in the nitrogenous constituents (urea, uric acid and creatinine) of the blood. There is a consistent increase in the clearance of the creatinine content, in contrast to wide variations of the clearance capacity which occur during infection. There is little or no change in the non-nitrogenous constituents, such as sugar, phosphorus, lipids and calcium, except, occasionally, for a slight increase, which in turn depends on an increase in concentration of the blood. There occurs no significant decrease in the lipids of the plasma such as is seen in the presence of acute infections. There is usually an alteration in the acid-base equilibrium of the blood which tends to produce slight alkalosis. Marked alkalosis may be noted. It has been concluded that fever characterized by severe dehydration and hyperventilation induces pronounced alkalosis. The degree of alkalosis which approaches critical levels is dependent on the severity of the dehydration and on the extent of hyperventilation. Opinions vary as to the effect on the hemal concentration of the chlorides. Some investigators claim that there may be a marked decrease in this concentration, whereas others declare that there is no significant change. If salt or a weak saline solution is administered by mouth during treatment, the hemal concentration of chlorides diminishes very little. If no sodium chloride is administered, profuse sweating and a diminished concentration of chlorides are to be expected. It has been noted that in seven cases the development of jaundice followed prolonged fever therapy. Two significant effects common to each case were found: (1) the increase in the icteric index was accompanied by a low value for the serum chloride and a diminished excretion of urinary chlorides and (2) the jaundice could be relieved only by the administration of large amounts of sodium chloride, and not by the administration of carbohydrates. Proper attention to the chloride and water balances "is apparently the most important factor in the technic of administering prolonged fevers." The oxygen content and oxygen-combining power of venous blood are increased. Opinions also vary as to the effect of artificial fever on the agglutinins of the blood, but the agglutination titer is generally within normal limits. The action of complement-fixing antibodies is temporarily diminished, but there is no change in the opsonic index. In studies on the effects of fever, great modifications in the antibodies of normal and syphilitic patients following fever were found. Studies made by means of a calorimeter on the mechanism of heat loss from the human body showed that "the mechanism for heat loss is adequate to care for twelve times the basal heat production" and that "spontaneous fever is due almost entirely to malfunction of the mechanism for heat loss."

Other Effects.—Examination of the effects of fever therapy on the gastric contents reveals a sudden decrease in the amount of chlorides and an increase in the amount of lactic acid. The urine is increased in amount, but temporary oliguria generally occurs. The reaction of the urine is unchanged, but the urine may be slightly alkaline and its specific gravity may be increased. The basal metabolic rate is increased approximately 7 per cent for each degree of fever induced. Cold fluids taken by mouth produce fluctuation in the gastric temperature but do not appreciably affect the general temperature. The comparison of the temperatures observed in the median antebrachial vein, rectum, uterine cervix, Hunter's canal, bladder and spinal canal indicate that records of the rectal temperature provide an accurate index to the temperature of the deep tissues. After each treatment there may be a temporary loss of weight as a result of loss of fluids unless sufficient fluids are taken by mouth, but this lost weight is quickly regained and after a course of fever therapy a patient usually retains his original weight or even gains weight.

PATHOLOGIC CHANGES

Hemorrhagic encephalitis and hemorrhagic pneumonitis have been noted in some instances in which extreme hyperpyrexia was induced. Deterioration of, and hemorrhage into, the cortex of the suprarenal gland may occur after induction of such hyperpyrexia. In the large viscera of laboratory subjects killed by hyperpyrexia there were found regions of focal degeneration and cloudy swelling. It has been observed that no demonstrable changes in nerve tissues occur in laboratory animals whose temperatures were elevated to 111.5 to 111.9 F. for from thirty-three to seventy-five minutes. Rabbits which were subjected until death to febrile temperatures not exceeding 108.3 F. were seen to have peripheral nerves characterized by degenerative changes of the reversible type. Intensity of the changes was directly proportional to the degree of febrile temperature induced in each animal. In rabbits subjected to intermittent periods of induced fever (during which the average bodily temperature varied between 106.1 and 107.8 F. for a total of from eighteen to fifty hours with one week of recovery time allowed between the last exposure and the time of killing) the peripheral nerves exhibited only mild intensities in the reversible types of degenerative change. If the bodily temperature of the animals was raised to 107.6 to 108.5 F. for eight hours and thirty days intervened between the time of exposure and the time of killing, the nerves showed a marked return to the normal status. Inferential evidence presented with this study indicated that regional anoxia was a contributing factor of considerable importance in the causation of the degenerative changes in the peripheral nerves observed after artificial fever.

At necropsy after death resulting from the induction of artificial fever, as observed in the experimental laboratory and elsewhere, pathologic lesions have been found which are similar to the lesions discovered at necropsy after death caused by the administration of nitrous oxide anesthetic. These lesions would seem to indicate that death may result from anoxia.

BACTERICIDAL EFFECTS

Neisseria gonorrhoeae is generally destroyed by a temperature of from 106 to 107 F. (41.1 to 41.6 C.) in from six to twenty-seven hours. In a high percentage of cases of syphilis, dark field illumination wi-

not reveal the presence of Spirochaeta pallida after the patient has been treated with fever induced by physical means. Mycobacterium tuberculosis, Streptococcus haemolyticus or Streptococcus mitior when exposed to temperatures within physiologic ranges in vitro show no cultural changes. Micrococcus catarrhalis, Haemophilus conjunctivitidis, Haemophilus influenzae, Brucella abortus, Escherichia coli, Eberthella typhosa, Streptococcus haemolyticus, Streptococcus viridans and Diplococcus pneumoniae (type I and type III) usually resist a temperature of 107 F. (41.6 C.) in vitro for twenty-four hours; an occasional strain shows some reduction in number.

DESCRIPTION OF APPARATUS

There are various devices for the production of artificial fever. The most common devices used at present are the air conditioned cabinets, luminous heat cabinets, air conditioned cabinets used in conjunction with short wave diathermy, electric blankets and zipper bags or blankets used in conjunction with short wave diathermy.

Air conditioned cabinets produce a rise in the bodily temperature by circulating hot, humid air over the body. Hyperpyrexia is produced by the heated air. The dry air temperature of these cabinets is usually maintained at between 110 and 130 F., and the humidity is maintained at as high a percentage as possible (from 80 to 95). These cabinets are heated by small radiant heaters similar to the units found in the household electric heater. The humidity may be maintained by a 1,000 to 2,000 watt immersion heater placed in a pan of water. The air is circulated by means of small fans. This type of cabinet can be used with entire satisfaction to produce artificial fever without the aid of a diathermy apparatus. Several such cabinets are on the market.

There is a luminous heat cabinet which is similar in its action to the air conditioned type except that it is heated by four or five 200 watt carbon filament bulbs situated in the top of the cabinet. It has a fan and humidifying pan with which to circulate and humidify the air. This type of cabinet can be constructed easily by any hospital carpenter for from $150 to $250.

Short wave diathermy machines have become very efficient in the production of artificial fever. The most satisfactory means of using short wave diathermy is to employ it in conjunction with an air conditioned cabinet. Fever is induced by means of the short wave electromagnetic cable or electrostatic plates; the bodily temperature is maintained by means of the air conditioned cabinet.

High frequency currents, short wave diathermy and, likewise, conventional diathermy can be used in conjunction with blanket packs or bags with slide fasteners. This procedure is satisfactory for administering short sessions of fever but is not satisfactory for the production of prolonged high fever. The blanket pack or the bag with slide fastener exerts an extremely confining effect on the patient, so that it is almost impossible for him to withstand many hours of fever. Various kinds of electric blankets, some of which are designed in the form of a large sleeping bag, have been constructed for use in fever therapy. They are less expensive than cabinets, but their great disadvantage is that the patients enveloped within them are closely confined. These blankets, if employed at all, should not be used when a temperature of more than 103 or 104 F. (39.4 or 40 C.) is required. None have yet been approved by the Council on Physical Therapy of the American Medical Association.

Hydrotherapeutic Methods.—The production of fever by means of hot baths is still being used successfully by some investigators. Although prolonged hot tub baths are enervating, they elevate the patient's temperature rather rapidly and may maintain it at a fairly high level for from one to two hours. After the fever has been induced by means of the bath it can be maintained by means of blankets or, better still, by means of a simple radiant heat cabinet.

The simple tub bath is as inexpensive and uncomplicated as any method of producing fever. It seems likely that as physicians continue their search for simpler and better methods of producing artificial fever by physical means, they will more frequently elevate the temperature by means of hot baths and maintain it with a radiant heat cabinet.

In administering the hot spray bath, the nude patient is placed in a cabinet in the supine position with his head protruding from one end, as if he were lying in an air conditioned or other type of heat cabinet. He is then sprayed with a series of very fine jets of nebulized hot water, the temperature of which is controlled by means of a thermostat. This spray cabinet will produce a rapid rise in bodily temperature if the temperature of the water can be maintained at the proper degree. One supposed advantage of this method is the fact that the thermostat can be switched immediately, thus releasing a momentary spray of cold water. The brief spray of cold water will exert a refreshing effect on the patient; at the same time, if the switch to the cold water is maintained for a brief time only, there will be an increase in the bodily temperature instead of a decrease. Apparently the momentary contraction of the peripheral capillaries caused by the cold spray drives the warm peripheral blood into the splanchnic regions, thus producing an additional and a more rapid increase in the systemic temperature. The chief detriment to the use of the spray cabinet is that the operator must depend on a general water supply as the source of heat, and it is rarely possible to obtain a constant flow of sufficiently hot water.

Other Conduction Methods.—A simple method of inducing hyperpyrexia by wrapping the patient in blankets and rubber sheeting has been used. With this method, no source of heat other than the natural heat of the body is utilized; however, four or five hours is necessary in which to elevate the bodily temperature to 104 F. (40 C.), which would seem to be an unnecessarily long period of discomfort before the required high temperature is achieved. If this method is to be used, it would seem expedient to use at least a few hot water bottles in the patient's wrapping in an attempt to induce the fever more rapidly.

In using the hot water bottle and blanket method, the patient is simply wrapped in a number of thick blankets and surrounded by a number of hot water bottles. The great disadvantage of any blanket method of inducing hyperpyrexia rests in the fact, as has been indicated, that nearly all patients are rendered extremely uncomfortable by the confinement of their limbs occasioned by the necessarily tight wrapping of so many heavy coverings.

PERSONNEL

A carefully trained team consisting of technicians and a physician is essential to the safe conduct of fever therapy. The personnel of the fever therapy depart-

ment is almost as important as the personnel of the operating room. A competent physician familiar with all the reactions which can be evoked by this type of therapy should be in attendance at all times during the treatment. The treatments should be administered by registered nurse-technicians who have been trained for at least one month or six weeks in a well organized fever therapy department of a hospital or under the close supervision of some person who has had such training. It has been said "The percentage of cooperative patients is directly related to the expertness and the tact of the nurse in charge." Failure to achieve a measure of success with fever therapy in many institutions arises from the fact that the attending nurses have not been adequately trained and familiar with the physiological principles that are essential to effective treatment. For many reasons the use of fever therapy should be confined to institutions. It must be borne in mind at all times that fever therapy is not without danger. Though it is entrusted to a corps of highly trained workers, serious complications can and do occur during its administration.

TECHNIC

Selection of Patients.—Emphasis cannot be laid too strongly on the need for careful selection of patients. The patient should be subjected to a careful physical examination before treatment, and if there is any degree of hypertension, cardiac disease or severe debility he should be rejected. Functional disorders of the heart need not contraindicate fever therapy, and under satisfactory control patients with diabetes may also be accepted. Pulmonary tuberculosis may not be a contraindication per se, but the associated respiratory involvement may prevent the satisfactory elevation to, and maintenance of, high temperature. Fever therapy is not contraindicated by the presence of subacute carditis or inactive rheumatic heart disease; on the contrary, it may be of benefit in such conditions. In general, it might be said that any contraindication to major surgical procedures is likewise a contraindication to this type of therapy.

Management of Patients During Treatment.—Fever therapy is not tolerated uniformly by all patients; as is the case with other types of therapy, toleration depends on the reactions of the individual patient. The average person should be told what to expect of the treatment, should be enlightened as to the various physical changes that will occur and should be informed that the treatment is severe but not intolerable. Persons who have no idea of what to expect during the fever treatment frequently become extremely nervous, so that they cannot be controlled for the desired length of time. There is a certain group of extremely nervous, easily excitable persons who will not tolerate the treatments.

The most common untoward results observed during fever therapy are headache, restlessness, nausea, vomiting, tetany and muscle cramps. Heat prostration may occur. Restlessness requires sedation, which may be repeated every two or three hours. There is considerable variance of opinion concerning the best sedative, but in the experience of most workers codeine, pantopon, dilaudid and morphine sulfate have been satisfactory. It has been contended that carbamide sedatives are more satisfactory for basic sedation than the barbituric acid group of drugs. The latter are respiratory depressants and may also increase the danger of hemorrhage and patchy necrosis of the central nervous system. Such hemorrhage and necrosis may be produced by anoxia which often exists during fever therapy or simply by the barbiturates when administered in toxic doses. Therefore, the combination of barbiturates and fever seems ill advised. It seems essential to keep the patient quiet but never in a state of narcosis sufficient to prevent his reacting to questioning. Nausea and vomiting may be controlled by intravenous injections of from 500 to 1,000 cc. of 5 per cent dextrose and 1 per cent sodium chloride in solution during the treatment. Tetany may be corrected readily by the intravenous injection of 10 cc. (approximately 2½ fluidrachms) of calcium gluconate. From a study of the metabolism of chloride and water it has been concluded that the maintenance at a high level of the patient's intake of fluid and sodium chloride is of the utmost importance. For the average six to ten hour period of fever treatment, a total intake of from 3,000 to 5,000 cc. (3 to 5 quarts) of fluid has been found effective. An intake of sodium chloride of at least 20 Gm. (approximately 5 drachms) will cover the chloride loss in perspiration for the average treatment. The maintenance of fluid and chlorides may be accomplished easily by having the patient drink from 3 to 6 liters of a solution of 0.3 or 0.6 per cent sodium chloride, iced, during the session of fever. The patient may also be allowed to drink sweetened tea, orange juice, lemonade and carbonated beverages. He should be instructed to ingest a meal rich in carbohydrates on the night before a fever treatment. In some cases an intravenous injection of from 500 to 1,000 cc. of a solution of 5 per cent dextrose in physiologic solution of sodium chloride should be made on the morning of treatment.

The skin of the patient should be observed frequently during treatment. The feet and legs may be protected by a covering of terry cloth placed in position at the beginning of the treatment. If a region of erythema appears on any part of the body, that region should be protected by a towel. If the erythema becomes more prominent, a cold cloth or a piece of ice may be applied. By observing such precautions and by elevating the patient's temperature gradually, one can prevent what might otherwise develop into severe burns.

When air conditioned cabinets are used, the dry air temperature should be maintained between 110 and 130 F. (43.3 and 54.4 C.) in association with high humidity and low air velocity. With this procedure, there is little necessity for covering the patient and burns of the skin are infrequent.

Episodes of delirium occur not infrequently during prolonged high fever. Delirium, unless it is violent, does not contraindicate continuance of the treatment.

There is usually an increased oxygen saturation of the venous blood during the early part of a fever session but later if there is circulatory failure there may be a severe anoxemia and anoxia. The factors producing this anoxia are increased temperature of the blood and the resulting increased demand for oxygen in the tissues and, in some instances, failure of circulation. Oxygen inhalation is an important factor during fever treatments. At one time oxygen tents were used over the heads of patients in fever cabinets in an attempt to increase the effectiveness of therapy, the assumption being that the high oxygen saturation of the blood thus obtained might be an important factor in the curative effect of the fever. With bodily temperatures of from 101.8 to 105.9 F. (38.8 to 41.1 C.), the oxygen content of the venous blood was observed to be considerably

elevated. When the bodily temperature was elevated and oxygen was also administered, the percentage oxygenation of the hemoglobin frequently was found to exceed 95; however, a clinical estimate of the procedure indicated that the combination of oxygen and fever was only slightly more effective against disease than was fever alone. It was decided, however, to consider the use of oxygen in conjunction with fever therapy only from the standpoint of additional safety to the patient. The oxygen tent was found cumbersome and difficult to use, because most patients objected seriously to being entirely enclosed. The use of nasal catheters has been suggested, as has also use of the so-called face tent.

More recently, use of one of the two types of the new Boothby-Lovelace-Bulbulian oxygen face masks has been found effective. The mask is laid lightly over the patient's nose and he is permitted to inhale oxygen at intervals during one half to three fourths of the entire treatment. The adjustment is so arranged as to permit a partial rebreathing and a partial admixture of atmospheric air. *Patients do not object to this type of mask,* because it is light, readily applied and easily lifted off at any moment to allow sponging of the face and administering of fluids by mouth. The intermittent administration of oxygen during all fever treatments is an important additional safety factor in the prevention of the dangerous after-effects of anoxia that have been so clearly described by a number of investigators.

There should be a well trained fever therapy nurse in constant attendance on the patient. At no time should she be more than a few feet away. The pulse rate, temperature and respiratory rate should be recorded every fifteen minutes for the first hour of therapy and every ten minutes thereafter. A careful record should be made of the amounts of fluid intake and also of the reactions of the patient. The temperature should be taken during the first hour by both mouth and rectum and thereafter by rectum exclusively. Electrical indicating thermometers are extremely convenient and satisfactory and their use allows the nurse-technician to give more attention to the patient. The blood pressure should be recorded every hour during the treatment. Any untoward reactions of the patient seen by the technician should be reported immediately to the physician in charge, who should be within calling distance at all times.

COMPLICATIONS

Mention already has been made of the reactions that may occur during a session of fever, such as headaches, nausea, vomiting, tetany and abdominal cramps. Nausea and vomiting also may be present during the evening after treatment, although they are usually relieved within twenty-four hours. Herpetic lesions on the lips and in the mouth, nose and pharynx may be so severe as to render eating and drinking difficult for a time. These lesions tend to disappear even though fever treatments are continued at regular intervals.

Occasionally superficial burns occur, especially on the arms and chest. However, these usually do not interfere with subsequent sessions of fever, and they can be avoided in practically all cases if the precautions previously mentioned are followed.

One of the most serious complications is circulatory collapse with a possibly fatal termination. Circulatory disturbance may occur during treatment in spite of the more careful antetherapeutic examination and even though the condition of the patient is apparently good during the treatment. In cases of circulatory collapse, the usually accepted treatment for shock is administered. Not only a rise of the temperature above safe physical limits but other serious consequences may be avoided by discontinuing treatment whenever any of the following conditions are found: (1) a systolic blood pressure of less than 80 mm. of mercury, (2) a pulse pressure of less than 20 mm. of mercury and (3) a pulse rate of 160 beats or more which is constant for more than thirty minutes. Often in the presence of these conditions cooling the patient momentarily may result in an improvement that will last throughout the treatment. It is now known that circulatory collapse occurring during fever therapy may be caused by the loss of fluids resulting from excessive perspiration. If the systolic blood pressure recedes below 80 mm. of mercury during the treatment, intravenous injection of from 500 to 1,000 cc. of physiologic solution of sodium chloride containing 5 per cent dextrose should be started at once. This is a most important safety measure; it will often permit continuation of treatment by replacing the lost fluids and by raising the blood pressure to within safe limits.

Another complication of a serious nature, infrequently encountered, is heat stroke. The patient's temperature rises suddenly to 107 F. (41.6 C.) or above. The pulse becomes hard, but its rate is not increased in proportion to the elevation of temperature. The blood pressure increases and coma and pulmonary edema may suddenly develop. The patient should be removed from the cabinet immediately and cooled by means of a tepid sponge bath and by a fan which blows cool air directly on the body. This procedure is considered preferable to the use of ice baths, which may contract the peripheral capillaries and lessen heat radiation. If pulmonary edema and apparent cerebral edema occur, the patient should receive a solution of hypertonic dextrose (50 per cent) by intravenous injection or a venesection should be done. The temperature may rise rapidly to 110 F. or more, with fatal results, or return to normal. If it returns to normal, care should be taken that the patient's condition does not proceed to a state of shock accompanied by a subnormal temperature.

THERAPEUTIC INDICATIONS

As is the case with many new therapeutic agents, artificial fever has been recommended for the treatment of a large number of diseases. As mentioned previously, it has been used for no less than fifty different ones. Space does not permit detailed consideration of the use of artificial fever produced by physical means in the treatment of all the conditions for which it has been recommended or used, which are as follows: adiposis dolorosa, allergic dermatitis, bronchial asthma, bronchiectasis, Buerger's disease, cerebral atrophy complicated by chronic otitis media, chorea, chronic sinusitis, dermatitis herpetiformis, epidemic encephalitis, epilepsy, infections of the gallbladder, gonorrheal arthritis, gonorrheal corneal ulcer, gonorrheal endocervicitis, gonorrheal epididymitis, gonorrheal prostatitis, gonorrheal salpingitis, gonorrheal urethritis, pelvic inflammatory disease, Hodgkin's disease, infectious arthritis, interstitial keratitis, subacute iritis, meningococcic septicemia, multiple sclerosis, mycosis fungoides, optic atrophy, osteogenic sarcoma, osteomyelitis, Parkinson's syndrome, peripheral vascular disease, psoriasis, psychoses, radiculitis, Raynaud's disease, rheumatic fever, sciatic neuritis, scleroderma, syphilis, syphilitic meningitis, ocular syphilis, syphilis of the nervous system, trichinosis, tumor and undulant fever.

It must be emphasized most strongly that fever therapy is probably of little or no value in the treatment of a number of these diseases. It would be distinctly dangerous to use fever therapy in some of the diseases for which it has been recommended. Among these may be mentioned: arteriosclerosis, subacute bacterial endocarditis, hepatic infections, pyelitis, staphylococcic septicemia and tuberculosis. Recent studies have added greatly to information on the treatment of some diseases by artificial fever; such studies should be consulted before artificial fever induced by physical means is employed to treat the disease in question.

Subacute Bacterial Endocarditis (Endocarditis Lenta).—It has been demonstrated definitely that, although there are some slight temporary relief of pain and a lowering of temperature following artificial fever therapy, no permanent beneficial effects can be noted after the hyperpyrexic treatment of patients having subacute bacterial endocarditis. Because of the presence of small vegetations of bacteria and fibrin on the endocardium, the marked increase in the velocity of the blood produced by fever therapy apparently increases the danger of embolism. Either cerebral or other embolism may occur. In addition it has been demonstrated that Streptococcus viridans is able to resist the highest temperature that the human body can tolerate. It is believed that any further attempts to use fever therapy for subacute bacterial endocarditis should be abandoned.

Bronchial Asthma.—Despite the fact that in a fairly large number of cases of intractable bronchial asthma fever therapy has brought about favorable results, it is felt that it should not be attempted in such cases unless all other means have failed. The results are frequently only temporary, and in some instances no improvement can be obtained. In no instance should fever therapy be attempted as an office procedure. It is the opinion of one investigator that hyperpyrexia of itself will be of only temporary, if indeed any, value but that when it is used in conjunction with other forms of treatment it is a most valuable adjunct.

Chorea.—The total number of cases of chorea treated by artificial fever induced by physical means is still too small to permit formation of any final conclusions. The studies do indicate, however, that the treatment of chorea by this method should be continued in well equipped institutions. Several investigators have found that choreiform movements cease in as many as 80 per cent of cases. Other investigators have reported more than 400 attacks of chorea for the alleviation of which the patients received fever therapy. Sixteen patients who had suffered from associated rheumatic carditis were also benefited. Comparative analyses of ninety-five cases in which the patients received fever therapy and of seventy-five in which they did not disclose a definitely lowered incidence of rheumatic manifestations among those patients who received fever therapy. Fever therapy was effective in cutting short an attack of chorea. The presence of associated active carditis was not a contraindication to its use; in fact, the carditis was perhaps benefited by it. The immediate results were excellent and recovery occurred in the majority of cases. The procedure of treatment for chorea has varied with different investigators, but in general it is believed that ten or twelve sessions of from two to three hours daily, with bodily temperatures maintained at from 104 to 105 F. (40 to 40.5 C.), form the procedure of choice. Some workers, however, have employed from four to six sessions, each of which was from five to eight hours in duration, maintaining the bodily temperatures between 104 and 105 F. (40 and 40.5 C.) and repeating these sessions every third or fourth day. Typhoid vaccine has been used with satisfactory results, the temperature being raised to 104 or 105 F. (40 or 40.5 C.) and maintained at a constant elevation for from five to six hours by means of a blanket pack. It is felt, however, that the fever therapy produced by physical means is more easily controlled and that children will accept and tolerate it more readily.

Gonorrhea.—The effects of artificial fever therapy produced by physical means on gonorrhea and its complications are conclusive. Reports by several investigators are available concerning the pyrexic treatment of gonorrhea in a large series of cases. More than 1,000 cases of gonorrhea treated by artificial fever induced by physical means have been recorded during the past five years. The percentage of remissions in the series of cases previously mentioned has been approximately 90. The rationale of the application of fever therapy to gonorrhea has been based of course on the thermolabile properties of the gonococcus.

When fever therapy was first used for gonorrhea, the patient's bodily temperatures were raised to from 106 to 107 F. (41.1 to 41.6 C.) and maintained at this level for six hours. The patient usually received from three to ten treatments, administered every third day. Later it was found that when gonorrheal infections were treated for periods equal to or slightly less than the thermal death time of the gonococcus, there was usually destruction of that organism. Many workers began to use fever sessions of long duration, the usual session being ten hours, maintaining the bodily temperatures at from 106 to 107 F. (41.1 to 41.6 C.). The duration of the treatment administered at 106.7 F. (41.5 C.) may be sufficient to equal 85 per cent of the thermal death time of the gonococcus and yet fail to result in a cure; on the other hand, treatment brief enough to equal only 10 per cent of the thermal death time occasionally results in a cure. The variation in effectiveness is probably influenced by the condition of the defense mechanism of the body. In the use of single fever sessions of ten hours' duration with bodily temperatures maintained at from 106 to 107 F. (41.1 to 41.6 C.), the results have been most satisfactory. In 94.6 per cent of ninety-nine cases there was remission after an average of 1.1 sessions, each ten hours in duration.

Since the introduction of sulfanilamide into therapeusis, the need for artificial fever in treating gonorrhea has become less; however, there remains a certain percentage of patients who cannot tolerate sulfanilamide or with whom sulfanilamide does not eradicate the disease. For these the combination of sulfanilamide and hyperpyrexia has proved most efficacious.

Gonorrheal Arthritis.—In most cases startlingly good results have been obtained with artificial fever in the treatment of gonorrreal arthritis. Most reports show that approximately 60 to 80 per cent of the patients become symptom free and that an additional 10 per cent are markedly improved; the other 10 per cent remain unimproved. The results are better when the treatment is instituted early in the course of the disease than when it is delayed until the disease has reached a chronic stage. The procedure used in the treatment of gonorrheal arthritis is the same as that for gonorrhea in general.

Other Gonorrheal Complications.—Gonorrheal ophthalmia has been shown to respond readily to fever induced by physical means, results revealing themselves in the form of subsidence of the inflammation, disappearance of the organism from the conjunctival tissues, acceleration of healing and a shortened stay in the hospital. Gonorrheal endocervicitis, gonorrheal prostatitis, gonorrheal salpingitis, gonorrheal pelvic inflammatory disease and gonorrheal endocarditis have been shown to respond favorably to prolonged high artificial fever. In the treatment of gonorrheal infections in the female, it has been found advantageous by some investigators to use local pelvic heating in conjunction with fever therapy. This may be done either by using vaginal applicators with which to heat the pelvis by a high frequency current or by using Elliott vaginal applicators with hot water as the thermal agent.

Infectious Arthritis.—About 30 per cent of one group of patients with infectious arthritis who were treated with artificial fever were significantly improved. The other 70 per cent exhibited little or no improvement. Fever sessions of short duration, during the course of which the bodily temperatures are elevated to from 101 to 103 F. (38.3 to 39.4 C.) by means of fever cabinets and hot baths, have been used; in conjunction with other corrective physical therapy they have appeared to be of benefit.

Meningococcic Septicemia.—Recoveries from this disease following the use of intense fever (of seven to ten hours in duration), with the temperature at 106.8 F. (41.5 C.), have been reported. Certain strains of meningococci were seen to exhibit a reduction in growth when they were maintained in culture at temperatures ranging from 40 to 42 C. (104 to 107.6 F.). Five strains were destroyed or greatly reduced in number within five hours or less. Fever therapy seems worthy of trial in selected cases of meningococcic infection.

Multiple Sclerosis.—The results of fever therapy in the treatment of multiple sclerosis for the most part have been unfavorable, although the number of cases reported is still too small to permit the formation of final conclusions.

Mycosis Fungoides.—After the induction of artificial fever by physical means, eight of ten patients having this disease were seen to obtain moderate improvement, an improvement, however, which apparently was only temporary.

Neuritis.—Low fever has been recommended as a safe and efficient means of treating neuritic and radicular pains.

Parkinson's Syndrome.—The use of artificial fever therapy for the condition causing this syndrome has not been particularly satisfactory. In seeking relief from this syndrome, it would probably be best to heed the statement "Fever therapy in the form of diathermy or malarial or bacterial injections seems to produce no permanent benefit. It may even do harm."

Rheumatic Fever.—It would seem that the treatment of rheumatic fever by artificial fever may sometimes be justified. After the use of artificial fever therapy in a small series of cases, patients often reported considerable relief of pain and swelling of the joints; there was a reduction in the leukocyte count and a decrease in the sedimentation rate of the erythrocytes.

In a comparative study of a small series of patients, some treated by means of artificial fever and some untreated, there was a striking reduction in the percentage of polyarthritis and also in the deaths from heart disease in the fever-treated group. Further analysis of the patients who had heart disease showed that the severity of the cardiac lesion was considerably greater in the untreated group; however, the two groups were small and the observation periods were not sufficiently long to warrant any final conclusion. The procedure used in the treatment of such patients usually consists of sessions of fever therapy four or five hours in duration with bodily temperatures maintained at from 104 to 105 F. (40 to 40.5 C.).

Syphilis (Early Primary).—Preliminary clinical investigations seem to indicate that, when artificial fever therapy is combined with chemotherapy, better results can be obtained than by the use of either form of therapy alone. However, in its present stage of development, fever therapy could not possibly be made available to the average patient having a primary syphilitic lesion. When the bodily temperature has been elevated to more than 105 F. (40.5 C.) for fifty hours in ten sessions of five hours each, this procedure being combined with thirty injections of an antisyphilitic chemical agent, cutaneous manifestations of the disease, including chancres, have been reported to respond with surprising promptness, so that no living, motile spirochetes can be found in any of the primary lesions after the first fever treatment. Progressive improvement in serologic reactions has appeared in the majority of cases. The results of treatment in control groups for which either fever therapy or chemotherapy was used indicated that neither of these methods alone was as effective as the combined procedure.

Dementia Paralytica.—The use of artificial fever produced by physical means in the treatment of dementia paralytica is becoming more and more extensive; however, there is still insufficient evidence available for the investigator to conclude that such fever will be more or less satisfactory than malarial fever. Most observers who have made careful comparative studies feel that fever produced by physical means offers a slightly higher percentage of immediate clinical remissions than does therapeutic malarial fever; however, it has been claimed by certain authorities in the field of syphilology that the relapse rate for physically induced fever will be higher than that for malarial fever. Certainly it will be several years before any final conclusions can be drawn; nevertheless, the best available comparative studies indicate that 70 per cent of patients with dementia paralytica who were treated with physically induced fever were immediately benefited by the treatment and that two years and eight months later 66.6 per cent of them remained improved; whereas, of a control group treated by malarial therapy, 63.3 per cent were improved immediately and two years and eight months later 56.6 per cent remained improved. These observations seem to indicate that the response of dementia paralytica to physically induced fever is apparently as well sustained as improvement brought about by therapeutic malaria. Much larger series of cases will have to be studied before final conclusions can be drawn.

Tabes Dorsalis.—It is generally agreed that patients with tabes dorsalis may be benefited by physically induced fever. Some investigators feel that tabetic pains and gastric crises respond more rapidly and with greater certainty to physically induced fever than to therapeutic malarial fever. Again it must be stressed

that the number of cases collected is not large enough to permit formation of any final conclusions. As additional evidence is collected, however, it becomes more apparent that physically induced fever may be of great value in the treatment of syphilis, particularly the tertiary manifestations of the disease.

Other Forms of Syphilis.—A number of investigators have reported encouraging results following the use of physically induced fever in the treatment of ocular syphilis, and there have been favorable reports also on the use of fever therapy for tabetic dementia paralytica, meningovascular syphilis and asymptomatic neurosyphilis.

Tuberculosis.—The study of the effect of fever therapy on dogs which had been subjected to experimental tuberculosis disclosed a temporary improvement, and as compared with that of control dogs, life was prolonged. Investigations, however, indicate that in the presence of tuberculosis, artificial fever therapy should be employed only with great care even in experimental studies. There is grave danger of doing harm to the patient if fever therapy is used for this disease. The study of this phase of the treatment of tuberculosis should for the present remain entirely in the hands of research workers.

Undulant Fever.—Several investigators have noted that in a small series of cases of undulant fever there has been a rather striking response to fever therapy. About 80 per cent of the patients treated exhibited definite clinical remissions with prompt disappearance of symptoms; however, the number of patients so treated is still insufficient to permit formation of final conclusions concerning the effectiveness of fever therapy. The procedure has been to administer five hour sessions of fever with bodily temperatures maintained at between 105 and 106 F. (40.5 and 41.1 C.); usually from one to three such treatments are necessary.

Conclusions with Respect to Diseases Treated.—Studies made to date seem to indicate that the chief sphere of usefulness of fever induced by physical means lies in the treatment of gonorrhea, both acute and chronic, and its complications. It would appear that artificial fever may be of value in the treatment of syphilis, particularly when it is combined with chemotherapy. While there is a suggestion that artificial fever produced by physical means may be helpful in the treatment of intractable bronchial asthma and in selected cases of chronic infectious arthritis, chorea and undulant fever, the clinical data are not sufficient to permit formation of any final conclusions. Its value in about forty other diseases remains to be proved. It seems to offer promise of considerable usefulness as a therapeutic agent.

CONCLUSIONS

Continued study has emphasized the fact stressed by the Council on Physical Therapy, namely that production of fever by physical means is strictly a hospital procedure, that it is essential that a well trained personnel be in complete charge of the work, that skilled nurse-technicians who have had at least one month's supervised training administer the treatments and that a physician be in constant attendance.

Patients to be treated by fever should be selected with as much care as those who are to undergo major surgical operations. The dangers that have been mentioned, embolism, hemorrhage and sudden death, are extremely rare when the administration of fever is in the hands of a competent, well organized group. However, it is to be expected that there will be a sh mortality resulting from a treatment that is as her as this one. If the treatments are given without pro control or are considered simple office procedures, th will be danger of harm to the patient or even dea

Opinions vary as to the best and safest means of p ducing fever. Almost any one of the methods descri in this article may be used with the confidence that will produce favorable results, provided the team workers has developed a good technic for the particu method to be employed.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUN ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LIST IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING, Secretary

CLAPP'S CHOPPED FOODS—SPINACH, GREEN BEANS, CARROTS, BEETS

Manufacturer.—Harold H. Clapp, Inc, Rochester, N Y

Description.—Canned chopped spinach, green beans, carro and beets, respectively, slightly seasoned with salt The veg tables are cut into small particles of relatively uniform size

Manufacture.—These products are treated essentially accor ing to the methods used in the preparation, canning and he processing of canned strained vegetables. Each vegetable in th Clapp's Chopped Food line, however, is not strained but passed through a chopping machine which consists of a seri of circular knives rotating between grates. The size of the foo particles produced is determined by the opening in the grate

Analyses (submitted by manufacturer).—

	Spinach, %	Green Beans, %	Carrots, %	Beet %

Carbohydrates other than crude fiber (by difference)	2 0	5 0	4 2	5 7

Calories.—Spinach 0.17 per gram, 5 per ounce. Green bean 0.3 per gram, 8 per ounce. Carrots 0 2 per gram, 6 per ounce Beets 0.3 per gram, 8 per ounce.

Vitamins.—No evidence has been provided the Council as t the vitamin content of these products. The method of prepara tion and processing is designed to retain the natural vitami values to the highest degree consistent with adequate and safe heating processes. Contact of the product with air durin processing is avoided as far as possible.

Claims of Manufacturer.—These products are intended pri marily for use in feeding infants who no longer require the vegetables to be strained or puréed.

CELLU BRAND BLACKBERRY JUICE

Distributor.—Chicago Dietetic Supply House, Inc, Chicago

Description.—Canned blackberry juice packed without added sugar.

Manufacture.—Fully ripened blackberries on which no spray material has been used are carefully selected, washed, sorted preheated and pressed through ordinary press cloth. The resu ing juice is run into cans and the cans are sealed and hea processed

Analysis (submitted by distributor).—Moisture 85 4%, to solids 14.6%, ash 0.4%, fat (ether extract) 0 6%, pro (N × 6 25) 0.1%, crude fiber 0.02%, carbohydrates other t crude fiber (by difference) 13.5%, invert sugar 12 7%, sucro 0.1%.

Calories.—0 6 per gram; 17 per ounce.

MEDICAL LICENSURE STATISTICS FOR 1938

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The Council on Medical Education and Hospitals of he American Medical Association presents herewith ıedical licensure statistics for the thirty-seventh conecutive year. The report covers the year 1938 and eals with statistics regarding (*a*) medical licensing oards of the United States, the District of Columbia, he terıitories and the possessions of the United States, *b*) examining boards in medical specialties, (*c*) oards of examiners in the basic sciences, and (*d*) the Jational Board of Medical Examiners.

Official reports have been contributed by the medical censing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands; the homeopathic boards of Connecticut, Delaware, Louisiana and Maryland; the eclectic examıng board in Arkansas; the twelve basic science oards in operation (Arizona, Arkansas, Colorado, Connecticut, the District of Columbia, Iowa, Minneota, Nebraska, Oklahoma, Oregon, Washington and Visconsin), the thirteen approved examining boards ı the medical specialties and the National Board of Medical Examiners. The homeopathic board of Louisiana did not license any one during the year. Likewise no physicians were licensed in the Canal Zone.

The cooperation of the officers of the boards in supplying complete reports has made possible this annual ompilation. The Council and THE JOURNAL wish to xpress thanks and appreciation to those who have upplied these data, for without their help such presenation would not have been possible.

Reports of all examinations and those licensed by ndorsement of credentials are carefully compared with he lists of graduates furnished by medical school officials, so that errors ın names of candidates, the medical school or the years of graduation are promptly corrected. In the occasional instance in which the applicant, according to the records, has not graduated or there is some irregularity, the state board is notified. Credentials of physicians coming from abroad aıe verified by direct correspondence with official agencies abroad so far as is possible. The statements regarding the medical education and licensure therefore of all physicians are accurate.

The data were also entered in the biographic file of physicians and others maintained by the Directory Department of the American Medical Association, thus serving a dual purpose. More than thirty licensing boards obtain from the Council verification of biographic data and other claims before granting a license or permission to take the licensing examination. This service is available to all boards.

The tables referring to medical licensing board results include figures regarding the number of candidates for medical licensure ın 1938, the number licensed and the number added to the profession.

LICENSES ISSUED

The first table presented in these statistics includes figures covering the number of licenses issued during the year in the various states, territories and possessions. There were 9,493 licenses ıssued, 6,548 on the basıs of examination and 2,945 by ıeciprocity and endorsement. In several states (table 12) the inteınship ıs a requisite for practice, but a physician is permitted to take the examination in most of these states and ıf successful his license is withheld until completion of his ınternship. Licenses are also withheld for lack of citizenship or minor technicalities. The figures,

(CONTINUED FROM PAGE 1697)

Virgin Islands licensed none by examination. Florida and Idaho grant licenses only on the basis of examination. Massachusetts and Rhode Island have no reciprocity privileges but endorse diplomates of the National Board of Medical Examiners. The total number licensed, 9,493, was 314 less than in 1937 but 460 more than in 1936 and 1,583 more than in 1935. On the basis of examination the figures decreased 73 and those licensed by reciprocity or endorsement decreased 241 compared with the figures for 1937. The 9,493 licenses issued do not, however, represent individuals, since several have been licensed in more than one state during the year. Nor does it represent additions to the medical profession at large, since the majority of the 2,945 licensed by reciprocity and endorsement, with the exception of those licensed on the basis of foreign credentials, and many of the National Board diplomates, have migrated from other states. Table 8 shows how many of those licensed were never before registered and therefore represent the number added to the medical profession.

TOTAL EXAMINED

In table 2 are included figures referring to those examined for medical licensure by individual states throughout the year, giving the number who passed and who failed in each state. There were 7,454 examined, of whom 6,582 passed and 872 failed, representing sixty-seven four year approved medical schools in the United States and eight of the medical schools of Canada, seventy-nine faculties of medicine and seven licensing corporations of other countries, eleven medical schools now extinct, eight unapproved institutions and several osteopathic colleges. Two undergraduates were examined. Osteopaths who were granted the privilege to practice medicine, surgery or both by the medical boards are included in these statistics, eliminating, for instance, those osteopaths in California who were granted privileges as physicians and surgeons by the osteopathic board. There were 5,606 graduates of approved medical schools in the United States examined, of whom 2.9 per cent failed; 163 graduates of approved Canadian medical schools, 9.2 per cent of whom failed, 1,166 graduates of schools outside the United States and Canada, principally in Europe, with 38.6 per cent failures, thirteen who graduated from schools now extinct with 69.2 per cent of failures, and 504 from unapproved and osteopathic schools and two undergraduates, of whom 47.0 per cent failed. These 506 represented 163 graduates of osteopathic schools, of whom 101 passed and sixty-two, 38.0 per cent, failed; 341 graduates of unapproved schools, of whom 166 passed and 175, 51.3 per cent, failed, and two undergraduates, one of whom failed. The latter were examined in Mississippi and New Jersey. Graduates of osteopathic schools were examined by the medical boards of nine states—Colorado, Connecticut, District of Columbia, Massachusetts, New Hampshire, New Jersey, Oregon, Texas and Virginia—while graduates of unapproved schools were examined in twelve states and Hawaii—Arizona, Arkansas, Florida, Illinois, Massachusetts, New Jersey, New Mexico, New York, Ohio, Pennsylvania, Texas and Vermont. Of the 163 osteopaths, fifty-eight were examined in New Jersey, forty-one in Massachusetts, thirty-four in Texas and twenty-one in Colorado. Other states examined fewer than five. Of those graduates of other than recognized schools, Massachusetts examined 223, Illinois sixty-four, Ohio thirty-two and New Jersey seven. All other states examined fewer than five. Osteopaths in Colorado, Massachusettts, New Hampshire, New

ined in ten states. The highest percentage of failures was 27.3, representing the University of Western Ontario Medical School; of eleven examined, three failed.

Nineteen medical schools had no failures before state licensing boards, namely the Universities of California, Colorado, Yale, Indiana, Kansas, Louisiana State, Harvard, Wayne, Washington, Albany, Duke, Cincinnati, Western Reserve, Oregon, Pittsburgh, South Carolina, Vanderbilt, Vermont and Wisconsin.

Thirteen graduates of medical schools now extinct were examined in four states with 69.2 per cent failures, a total of 1,166 graduates of medical schools outside the United States and Canada were examined in twenty-eight states, while 506 unapproved graduates and undergraduates were examined in twenty states.

In 1937, 7,325 were examined, of whom 6,594 passed and 731, 10.0 per cent, failed, as compared with 7,454 examined in 1938, of whom 6,582 passed and 872, 11.7 per cent, failed. There were 129 more examined than in 1937; twelve less passed but the failures increased 141. Elsewhere are given figures representing actual licentiates and additions to the medical profession.

GRADUATES OF 1936, 1937 AND 1938 EXAMINED FOR MEDICAL LICENSURE IN 1938

In table 3 are presented figures recording graduates of 1936, 1937 and 1938 examined for medical licensure in 1938. Altogether 6,118 were examined, 5,669 of whom passed and 449, 7.3 per cent, failed. Of these, 5,153 represented medical graduates of sixty-seven approved medical schools in the United States, of whom 5,043 passed and 110, 2.1 per cent, failed. Ninety-nine graduates of eight approved schools in Canada were examined, ninety-four of whom passed and five failed. There were 507 recent graduates of medical faculties outside the United States and Canada examined, of whom 322 passed and 185, 36.5 per cent, failed. There were also examined 359 graduates of medical schools not approved by the American Medical Association, of whom 210 passed and 149, 41.5 per cent, failed. Of

United States schools 2.1 per cent failed, of the Canadian graduates 5.1 per cent failed, of those educated outside the United States and Canada 36.5 per cent failed, and of graduates of unapproved schools 41.5 per cent failed. Of the United States graduates, the school having the highest percentage of failures, 10.7; was the State University of Iowa College of Medicine, whose graduates were examined in eight states. Ten per cent of the graduates of Meharry Medical College failed, while 16.7 per cent of the graduates of the University of Western Ontario Medical School failed. Twenty-eight schools in the United States had no failures among its recent graduates examined for medical licensure in 1938. Graduates of Rush Medical College were examined in thirty-two states, Northwestern graduates in thirty, Harvard and the University of Pennsylvania in twenty-one, and Loyola in twenty states. Two states licensed recent graduates of Wayne, Albany and Pittsburgh. The greatest number examined by any one state was New York, 1,014, Pennsylvania was second with 489, Illinois examined 451, California 379 and Ohio 322.

More than 100 were examined from sixteen schools, the highest being the 164 graduates each of Rush Medical College and the University of Illinois College of Medicine. Forty-five graduates of McGill University Faculty of Medicine were examined in nineteen states, while none from Laval University Faculty of Medicine were examined. Only five graduates of Yale during the years named were examined in five states and only thirteen graduates of Duke University School of Medicine, who were examined in eight states. Of these two schools, as shown in table 2, Yale had only nine graduates of all years examined, none of whom failed, and Duke fifteen, with no failures. The State University of Iowa had 107 graduates of all years examined with 10.4 per cent failures, while Meharry had forty-four examined with 11.4 per cent failures.

The figures shown in table 3 are subdivided by years in the following tabulation:

Graduates of	1936 Passed	1936 Failed	1937 Passed	1937 Failed	1938 Passed	1938 Failed
Medical schools in the United States	379	15	1,358	37	3,306	58
Medical schools in Canada	23	2	48	2	23	1
Foreign faculties of medicine	120	82	153	81	49	22
Unapproved medical schools and osteopaths	28	46	42	67	140	36
Totals	550	145	1,601	187	3,518	117

Of the 3,364 graduates of approved medical schools in the United States examined in 1938, fifty-eight failed, while thirty-seven of the 1,395 examined in 1937 failed and fifteen of the 394 examined in 1936 failed. The greatest percentage of failures was among the unapproved graduates.

FAILURES

In table 4 are presented for each state the number of candidates examined or granted licenses by endorsement or reciprocity and the number licensed after one failure and after two or more failures, these two groups being classified by indication whether the failure or failures have been in the state in which they are receiving a license or elsewhere.

Of the total number examined or endorsed, 9,527, 357 failed, 182 after one examination in the state in which they were licensed in 1938 and sixty-three elsewhere, while eighty-five failed more than once in the state awarding the 1938 license and twenty-seven elsewhere, leaving 9,170 licensed without ever having failed a medical licensing examination.

In the computation of this table it was noted that an osteopath was licensed in Massachusetts who was unsuccessful in passing the examination in Massachusetts on six occasions. Of the graduates of unapproved schools licensed in Massachusetts five failed four previous examinations, four had five failures before successfully passing, two failed nine times, one failed twelve times and another failed at fourteen examinations. New Hampshire granted a license by endorsement to a candidate who failed examinations in other states seven times. New Jersey issued licenses to two individuals with five failures. In New York, four had four previous failures, one failed five times and another had six unsuccessful examinations, while still another had seven unsuccessful examinations. Texas endorsed a candidate with seven failures.

* Alaska, Hawaii, Puerto Rico, Virgin Islands.

Twenty-two states licensed physicians who never failed a state board examination, while New York licensed 190, Massachusetts forty and New Jersey thirty-nine who previously failed. Licensure of candidates with failures occurred in twenty-six states, the District of Columbia, Hawaii and Puerto Rico but, with the exception of Massachusetts, New Jersey and New York, no state licensed more than fifteen.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

The number of physicians granted licenses to practice medicine and surgery without examination on presentation of satisfactory credentials are given in table 5. There were 2,902 so registered who presented licenses from other states, Canada and foreign countries, the certificate of the National Board of Medical Examiners, one of the government services, or other credentials.

Definite reciprocal relations are reported by twenty-four states. Twenty-six states, including five that have regularly established reciprocal relations, will register licentiates who present credentials which correspond to those required by their respective states at the time such licenses were issued. The medical practice acts of many give the examining board the privilege of using its discretion in determining the acceptability of a candidate. The reciprocity and endorsement policies of the various states are presented in table 6. In addition there is also indicated whether licenses are granted to diplomates of the National Board of Medical Examiners or to retired officers of the government services. Specific requirements such as professional practice, basic science certificate, oral examination and internship is recorded, as is also the fee demanded. Florida, Idaho, Massachusetts and Rhode Island do not have reciprocal or endorsement arrangements with any state. Massachusetts and Rhode Island, however, will register diplomates of the National Board of Medical Examiners by endorsement. Those desiring licenses by this method in Arizona, Arkansas, Colorado, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oklahoma, Oregon, Washington and Wisconsin are required to obtain a certificate from the board of examiners in the basic sciences before being eligible for licensure. Some states have additional requirements for graduates of schools outside the United States and Canada. Other requirements or exemptions are mentioned in footnotes.

In table 5 it will be noted that New York granted the greatest number of licenses by endorsement in 1938 (482), California the second highest (208), Michigan 166, New Jersey 152, Texas 138, Ohio 124, Illinois 110 and Massachusetts 105. All other states licensed fewer than 100 by this method. The largest group representing the same type of credentials were the 673 diplomates of the National Board of Medical Examiners. More than 100 physicians holding licenses in Illinois, Maryland, Missouri, New York, Ohio and Tennessee, respectively, were licensed in the various states. Twenty-nine physicians were certified on the basis of Canadian and foreign credentials. Only 175 physicians with New York licenses secured certificates elsewhere, while 482 were registered in New York on the basis of credentials. The number of physicians registered in New York on the basis of foreign credentials was twenty-one, whereas in 1937 it was 146. During the year the New York Board of Regents ruled that all would be required to pass examinations. The Regents' decision was appealed in a test case and the Supreme Court issued an order restraining the Regents from requiring foreign born physicians to pass an examination before practicing in New York. The Appellate Division of the Supreme Court supported the position taken by the Regents. The Regents are not endorsing any foreign licenses but requiring that all applicants take the regular medical examination.

One physician in the District of Columbia was licensed on the basis of German credentials by a special act of Congress. One was registered in Missouri on Canadian credentials. Five in New Hampshire were issued licenses by endorsement of credentials from Canada and Quebec one each and Germany three. The twenty-one in New York represented one with Russian credentials, two with Austrian and eighteen German degrees. One candidate in Vermont was certified on the basis of English credentials. Altogether, twenty-nine were licensed by five states.

Three states accepted credentials from Hawaii and Puerto Rico. One was endorsed by presentation of a Hawaiian license in California, and one in Montana and six in New York by endorsement of licenses issued in Puerto Rico. In addition, five were admitted to private practice in the Virgin Islands.

Not included in the table are forty-three osteopaths licensed by the board of medical examiners in five states, namely one in New Hampshire and thirty-seven in Texas granted the right to practice medicine and surgery, one each in Oregon and Wyoming licensed to practice osteopathy and surgery, and three granted this privilege in Wisconsin. Likewise excluded are those osteopaths granted licenses to practice medicine and surgery in California.

Of the five homeopathic boards in existence—Arkansas, Connecticut, Delaware, Louisiana and Maryland—only two issued licenses by endorsement, Connecticut and Delaware, which licensed two and one respectively. The Eclectic Board in Arkansas also registered one.

Diplomates of the National Board of Medical Examiners were registered in thirty-eight states, the District of Columbia, Alaska, Hawaii and Puerto Rico.

Maryland had the greatest number of its licentiates registered in any state, sixty-four, who were given the right to practice in New York. Alabama, Arizona, Connecticut, Delaware, Florida, Idaho, Montana, New Hampshire, North Dakota, Rhode Island, South Dakota, Utah, Washington and Wyoming had less than ten of their licentiates endorsed to other states. Two states had no physicians endorsed—Nevada and New Mexico. Arizona had only one endorsed, and Florida, New Hampshire, North Dakota, Rhode Island and Wyoming only two.

Included in the group at the side of the table listed as "U. S. Territories and Possessions" are Alaska, Hawaii, Puerto Rico and Virgin Islands.

A total of 2,902 physicians secured licenses by this method in 1938.

The physicians licensed by reciprocity and endorsement in 1938 and, in addition, forty-three osteopaths so licensed by medical examining boards are recorded by school of graduation and state or territory where licensed in table 7. All the four year medical schools in the United States (sixty-seven) and nine in Canada were represented. The largest number of graduates of any one school were from Harvard Medical School,

ninety-eight, who were licensed in twenty-nine states. Georgetown had eighty-seven licensed by this method in seventeen states, the University of Nebraska eighty-three in twenty-five states, and Northwestern seventy-seven in thirty states. Graduates of forty-two faculties of medicine in Europe and seven licensing corporations of Great Britain, three unapproved institutions and several osteopathic schools were licensed without examination. Graduates of thirty-six schools now extinct were also represented.

Of the 2,945 candidates licensed by reciprocity and endorsement, 2,668 were graduates of sixty-seven approved medical schools in the United States, forty-six graduates of nine approved medical schools in Canada, 115 graduates of European institutions, fifty-three of medical schools now extinct, twenty graduates of unapproved medical schools and forty-three osteopaths.

Some states have additional requirements for graduates of schools outside the United States and Canada.

1. 1st P, first papers required; +, full citizenship required.
2. In most cases there is a small additional recording or registration fee.
3. If state of original license grants similar privileges.
4. Internship accepted in lieu of one year's practice.
5. Professional practice required.
6. No professional practice required.
7. Just preceding application.
8. No basic science reciprocity—examination must be within the state.
9. Basic science certificate required either by reciprocity or examination in addition to basic science subjects of National Board.
10. Reserve officers not eligible.
11. Applicant's diplomate certificate must be dated not less than one year prior to the filing date in California of an application; applicant must also have been a resident of some state or territory of the United States for a period of at least one year after the date of his diplomate certificate.
12. Oral examination required when original license is ten or more years old.
13. Applicant must have resided in the state used as basis of application for one year after date on said certificate.
14. Oral examination required.
15. Unless in practice in another state for five years.
16. Six months of which must be just preceding application.
17. Practical, clinical examination required.

CANDIDATES ADDED TO THE PROFESSION

Licentiates representing additions to the profession during 1938 are recorded in table 8. The figures represent candidates examined in 1938 and licensed; also those examined in previous years whose licenses were withheld and issued in 1938, and those certified on the

basis of the certificate of the National Board of Medical Examiners, government services, Canadian and foreign credentials. In the main they represent recent graduates. Altogether, 6,252 were added to the profession. The number removed by death annually approximates 4,000. These figures indicate that at least 2,000 were added to the medical profession in 1938. It is assumed that the great majority of those licensed are in practice. It is interesting to note that, of 9,493 licenses issued throughout the year, 6,252 are actual additions to the medical profession. The largest number in any one state added to the profession was in New York, 1,204; Illinois added 464 and Pennsylvania 452, while South Dakota added only two. More than 300 were added in California and Ohio. Between 200 and 300 were added to the physician population of Maryland, Massachusetts, Michigan, New Jersey and Texas. Indiana, Louisiana, Minnesota, Missouri, Tennessee, Virginia and Wisconsin increased their population of physicians by between 100 and 200. Thirty-one states, the District of Columbia, Alaska, Hawaii and Puerto Rico added less than 100. Of the number of licentiates representing additions to the medical profes-

18. Same as charged Kansas.
19. Regular and Homeopathic boards.
20. Required of graduates of foreign medical schools.
21. Regular board.
22. Fee same as applicant's state charges if more than $50.
23. Oral examination required if applicant's state requires it.
24. If an applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required.
25. Internship accepted if served in this state.
26. Internship accepted—considered equivalent to two years' practice.
27. Five years' practice.
28. Conditionally.
29. A two year internship is accepted.
30. License by National Board certificate at examination fee of $15 unless holding a license from another state.
32. Clinical examination required.
33. Reciprocity applicants only.
34. Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established.
35. May be licensed after a special (written) supplemental examination.
36. Fee for license on basis of National Board certificate $25.
37. For matriculants after Oct. 17, 1937.
38. After July 1, 1939.
39. While in active duty only.
40. Permanent license withheld until completion of citizenship.

(CONTINUED FROM PAGE 1707)

sion during 1938, 5,755 secured this privilege by examination and 497 by the endorsement of credentials. Those licensed by endorsement consist of a few licensed on foreign credentials and to a large extent diplomates of the National Board of Medical Examiners. Figures for three previous years and 1938 are shown here for comparison:

Licentiates Representing Additions to the Medical Profession in Four Years

Year	Examination	Reciprocity and Endorsement	Total
1935	5,098	411	5,509
1936	5,546	628	6,174
1937	5,808	602	6,410
1938	5,755	497	6,252

In 1935 there were 5,098 added by means of examination and 411 by endorsement of credentials, a total of 5,509. In 1936 there were 665 more added than in 1935; in 1937, 236 more than in 1936 and 901 more than in 1935. In 1938 there were 158 fewer than in 1937 but seventy-eight more than in 1936 and 743 more than in 1935. Physicians were added in Alaska, Hawaii and Puerto Rico in 1938.

Table 9 records the licentiates representing additions to the medical profession grouped in nine geographic divisions in 1938; namely the New England, Middle Atlantic, East North Central, West North Central, South Atlantic, East South Central, West South Central, Mountain and Pacific states as well as Alaska, Hawaii and Puerto Rico. The largest number, 1,905, was added to the Middle Atlantic group, the East North Central 1,238, the South Atlantic 658, the West North Central 605, the West South Central 492, the Pacific 477, the New England group of states 407, the East South Central 325, and the Mountain division 118. Thirteen each were added in Hawaii and Puerto Rico and one in Alaska.

Totals	5,755	497	6,252

In table 10 those representing additions to the medical profession are arranged by schools; the same as those examined are listed in table 2, existing approved medical schools in the United States and Canada, foreign faculties of medicine, schools now extinct and unapproved schools and undergraduates.

The 6,252 physicians representing additions to the medical profession included graduates from the sixty-seven approved medical schools of the United States, eight approved schools in Canada, and others. The 119 and by reciprocity or endorsement sixteen. There were 668 graduates of foreign faculties of medicine, two from extinct medical schools and 282 unapproved graduates and undergraduates. Altogether there were 5,755 graduates of all schools examined, 497 by reciprocity or endorsement, a total of 6,252.

STATE REQUIREMENTS OF PRELIMINARY EDUCATION

Since 1918 the minimum requirement of preliminary education exacted by the Council on Medical Edu-

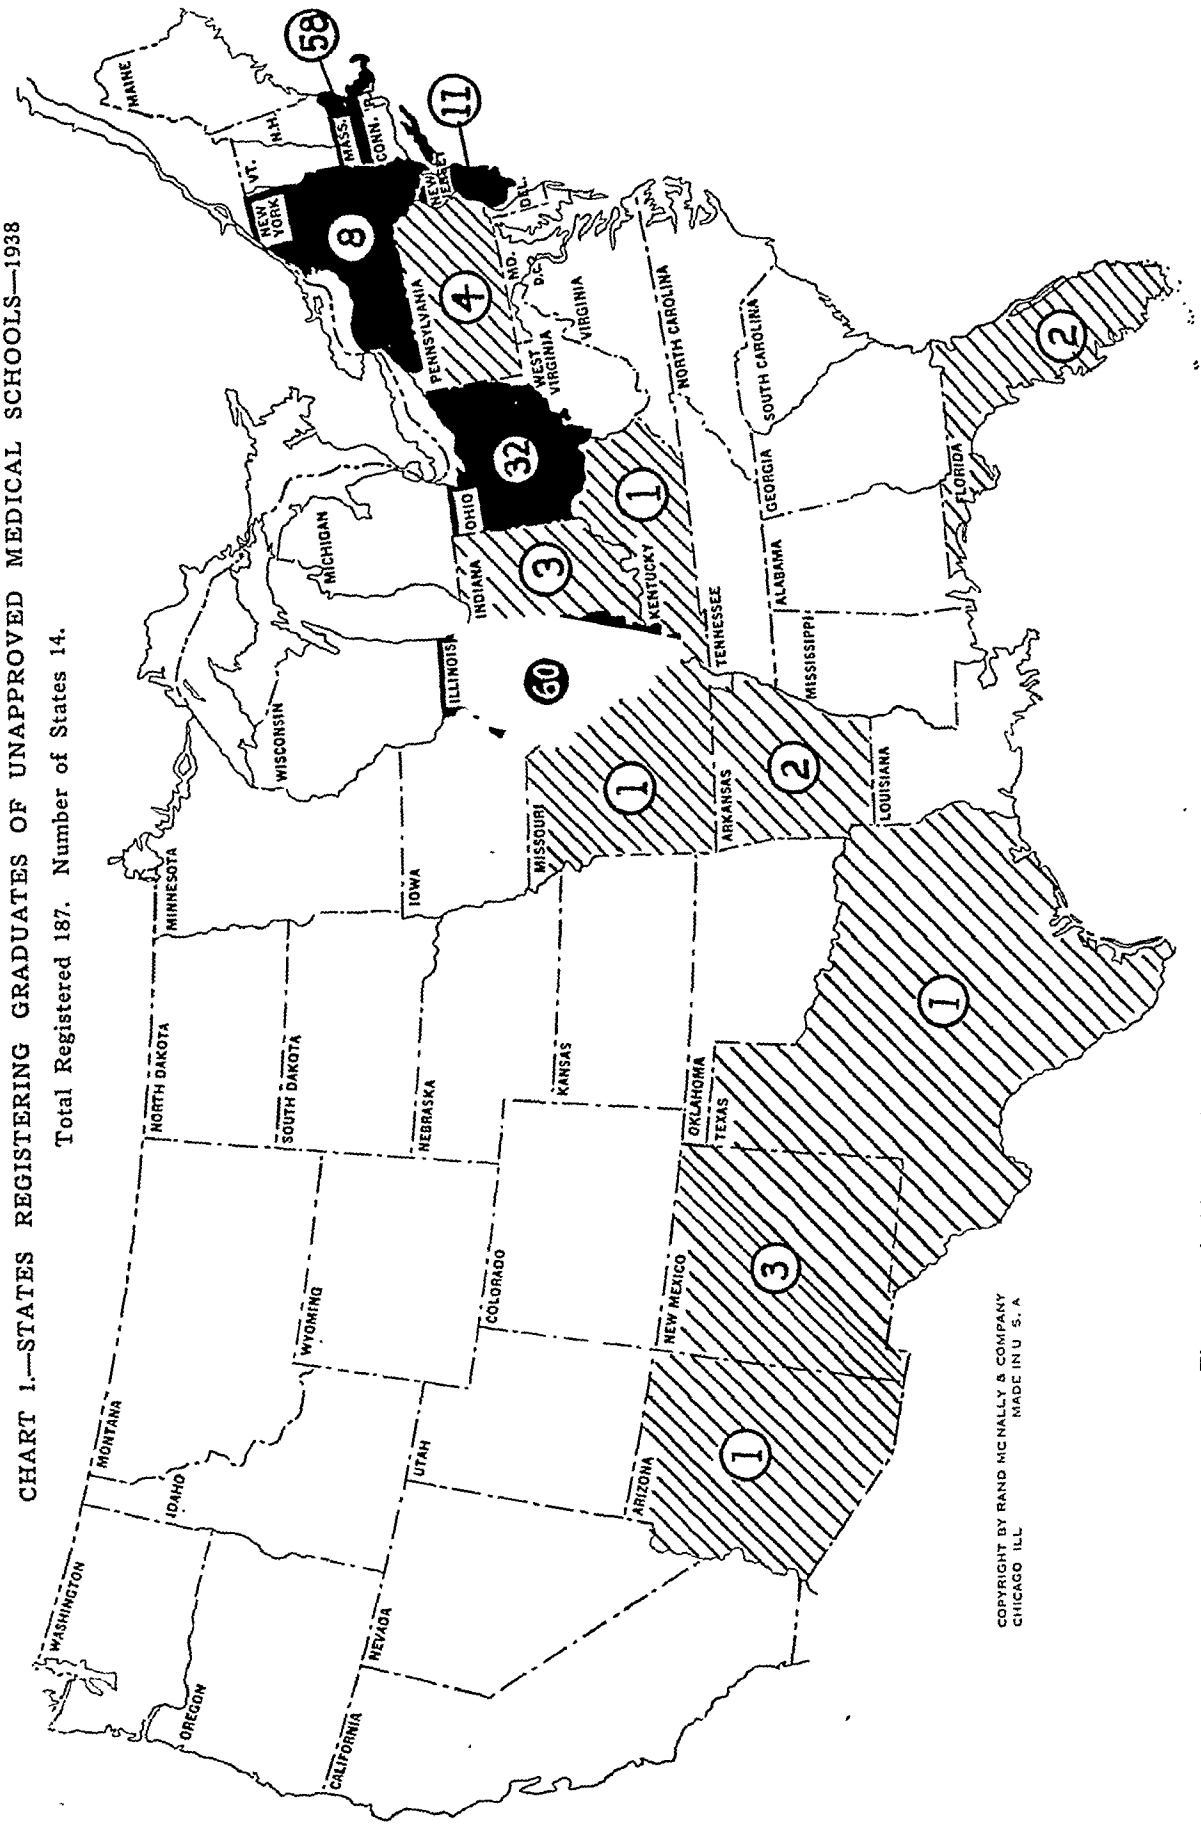
greatest numbers from any one school were 152 from the University of Illinois College of Medicine, 146 from Rush Medical College and 145 from Jefferson Medical College. Of the United States schools the Albany Medical College had the fewest, twenty-five, while only two were represented from the University of Alberta Faculty of Medicine. McGill University Faculty of Medicine added fifty-eight of its graduates to the physician population of the United States. From the United States schools there were 4,752 graduates added to the profession by examination and 413 by reciprocity or endorsement of credentials, a total of 5,165. From the Canadian schools 135 were added, by examination



cation and Hospitals in its Essentials of an Acceptable Medical School has been two years of college work. Six states, however, have not yet revised or amended their statutes to conform with these prerequisites, although with one exception these states do not as a rule license other than graduates of approved schools (table 11).

REQUIRED HOSPITAL INTERNSHIPS

The medical schools and licensing boards requiring or planning to require a hospital internship for state licensure and the M.D. degree, respectively, are shown in tables 12 and 13. The effective date of the requirement is also shown in table 13.

CHART 1.—STATES REGISTERING GRADUATES OF UNAPPROVED MEDICAL SCHOOLS—1938

Total Registered 187. Number of States 14.

The states in black registered more than 5 such candidates, those shaded 5 or less.

As revealed in table 12, twenty-one states, the District of Columbia, Alaska, and Puerto Rico require that all applicants for licensure possess a hospital internship. The first state exacting this requirement was Pennsylvania in 1914. The requirement in Alabama and Louisiana became effective in 1939. In addition, other states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants. These data are found in tables 6 and 20.

TABLE 11.—*State Requirements of Preliminary Training*

Two Years of College		
Alabama	Maine	Oregon
Arizona	Maryland	Pennsylvan'a

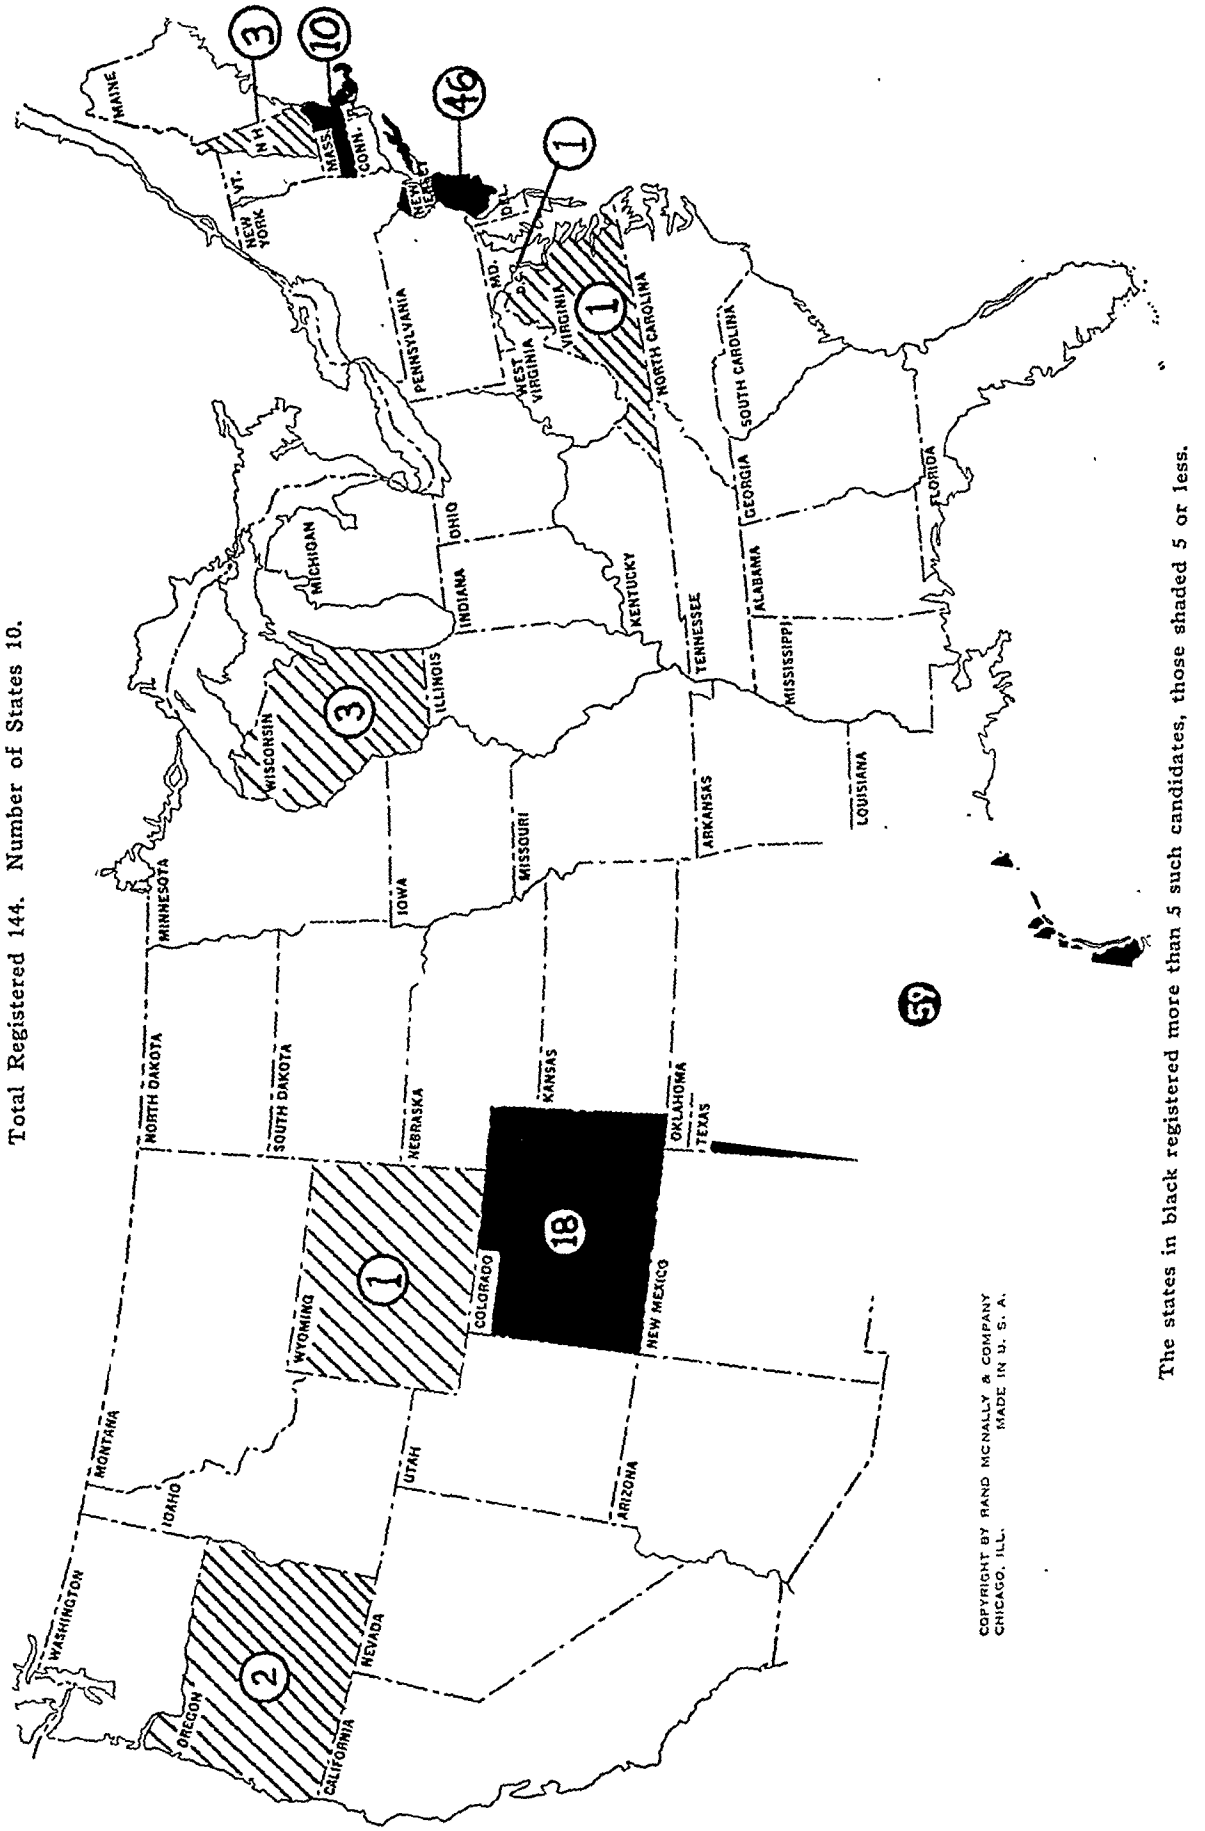
* Requires a two year internship

CANDIDATES EXAMINED FROM 1934 TO 1938 INCLUSIVE



In table 14 are listed the number of candidates examined in the various states, territories and possessions in the last five years, 1934-1938 inclusive, showing those who passed and failed. In this period New York licensed 4,793 candidates, Pennsylvania 2,511, Illinois 2,240, California 1,751, Ohio 1,557, Massachusetts 1,214, Michigan 1,143, New Jersey 1,056 and Maryland 1,036. Thirty-one states licensed less than 500 and eleven less than 100. The smallest number (nine) were examined in New Mexico. The percentage of candidates who failed in the examinations in the past five years is given in the last column. The percentage of failures in all states has increased from 8.4 in 1934 to 11.7 in 1938. In the five year period, 47.2 per cent of the applicants failed in Massachusetts. The high percentage in this state is due to the fact that by law the licensing board is required to admit to its examination the graduates of unapproved schools, many of whom repeatedly fail. Connecticut had 21.6 per cent failures in five years and Florida 19.7 per cent. The third highest proportion of failures was in New York with 21.3 per cent. The comparatively high percentage in this state is occasioned by the fact that New York admits a great many graduates of foreign medical schools to its licensing examination. Florida has no reciprocal relations with any state, all candidates applying being required to take the licensing examination. Graduates of earlier years experience difficulty in passing examinations. On the other hand, Arkansas, Nebraska, New Hampshire, New Mexico, North Carolina, Oklahoma and Oregon—seven states

CHART 2.—MEDICAL LICENSING BOARDS REGISTERING OSTEOPATHS TO PRACTICE MEDICINE, SURGERY OR BOTH—1938

Total Registered 144. Number of States 10.

The states in black registered more than 5 such candidates, those shaded 5 or less.

—had no failures Alabama, California, Colorado, the District of Columbia, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Michigan, Minnesota, Missouri, Montana, Ohio, Pennsylvania, South Carolina, South Dakota, Tennessee, Utah, Vermont, Virginia, Washington, West Virginia and Wisconsin—twenty-eight states—had less than 5 per cent of failures A total of 34,268 candidates were examined in the five years from 1934 to 1938 inclusive, of whom 30,871 passed and 3,397 failed, 9 9 per cent. These figures represent examinations given and not individuals A candidate who fails more than once in a given year is counted as only one failure, but should he fail in one of the succeeding years in another state he is counted in that year also Likewise, if a candidate fails and later passes, whether in the same or a later year, he is counted as failed and passed With a total of 3,397 failures for the five year period, it seems likely that there were approximately 30,000 individuals

TABLE 15.—*Registration—1904-1938*

Year	All Candidates Examined			Registered Without Written Examination	Total Registered

1935	6,435	5,891	9 1	2,195	8,046
1936	6 914	6,220	10 0	2,764	8 984
1937	7,325	6,594	10 0	3,186	9,780
1938	7,454	6,582	11 7	2,945	9,527

examined. It is to be assumed that the majority of those who fail are later reexamined and licensed in some state This figure gives a fair estimate of the number of physicians added to the profession each year. On page 1710 will be found exact totals for several years

REGISTRATION 1904 1938

A study of totals and percentages for thirty-five years (1904-1938) is presented in table 15 The number (6,582) who passed in 1938 was twelve less than in 1937 but 362 more than in 1936 and 890 more than in 1904 The number registered without examination, 2,945, was 241 less than in 1937 However, contrasting these figures with those for 1904 will show the great use being made of this system of licensure By both methods, examination and endorsement of credentials, 9,527 were registered, 253 less than in 1937. The number registered in 1937, 9,780, represented the largest number of candidates registered in thirty-five years Of those examined in 1938, 11 7 per cent failed as compared with 21 7 per cent in 1908 The failures in recent years represent to a large extent graduates of unapproved schools and foreign faculties. They are responsible also for the increase in the percentage of failures in 1938 as compared with the last four or five years.

While these figures represent those registered in the years given, they do not in all states represent the number licensed in a given year. Licenses are withheld in many states, as indicated in the text describing table 1.

TABLE 16.—*Graduates of Approved Schools and Others Registered 1922-1938*

Year	Graduates of Approved Schools		Others		Totals
	Number	Per Cent	Number	Per Cent	
1922	4,519	80 5	1,093	19 5	5,612
1923	5,196	80 8	1,234	19 2	6,430
1924	5 685	85 2	987	14 8	6,672
1925	6,313	86 4	994	13 6	7,307
1926	6,438	88 7	823	11 3	7,261
1927	6,410	89 4	759	10 6	7,169
1928	6,584	90 1	727	9 9	7,311
1929	7,002	91 0	697	9 0	7,699
1930	7 011	92 1	602	7 9	7,613
1931	6,931	92 8	541	7 2	7,472
1932	6,675	93 7	447	6 3	7,122
1933	6,774	93 7	456	6 3	7,230
1934	7,170	92 1	614	7 9	7,784
1935	7,362	91 5	684	8 5	8,046
1936	7,922	88 2	1,062	11 8	8 984
1937	8,371	85 6	1,409	14 4	9,780
1938	8 300	87 1	1,227	12 9	9,527

There appears to be no marked increase or decrease in the total number of candidates registered from 1904 to 1933, but from 1934 to 1937 the number registered has been markedly increasing although there was a decrease in 1938 of 253 as compared with 1937. However, the number licensed without examination since 1906 has been increasing, owing to the almost universal recognition of the certificate of the National Board of Medical Examiners The decrease in the number registered in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life Again in 1922 there was a notable reduction, this figure resulting from the small number that began the study of medicine in 1918

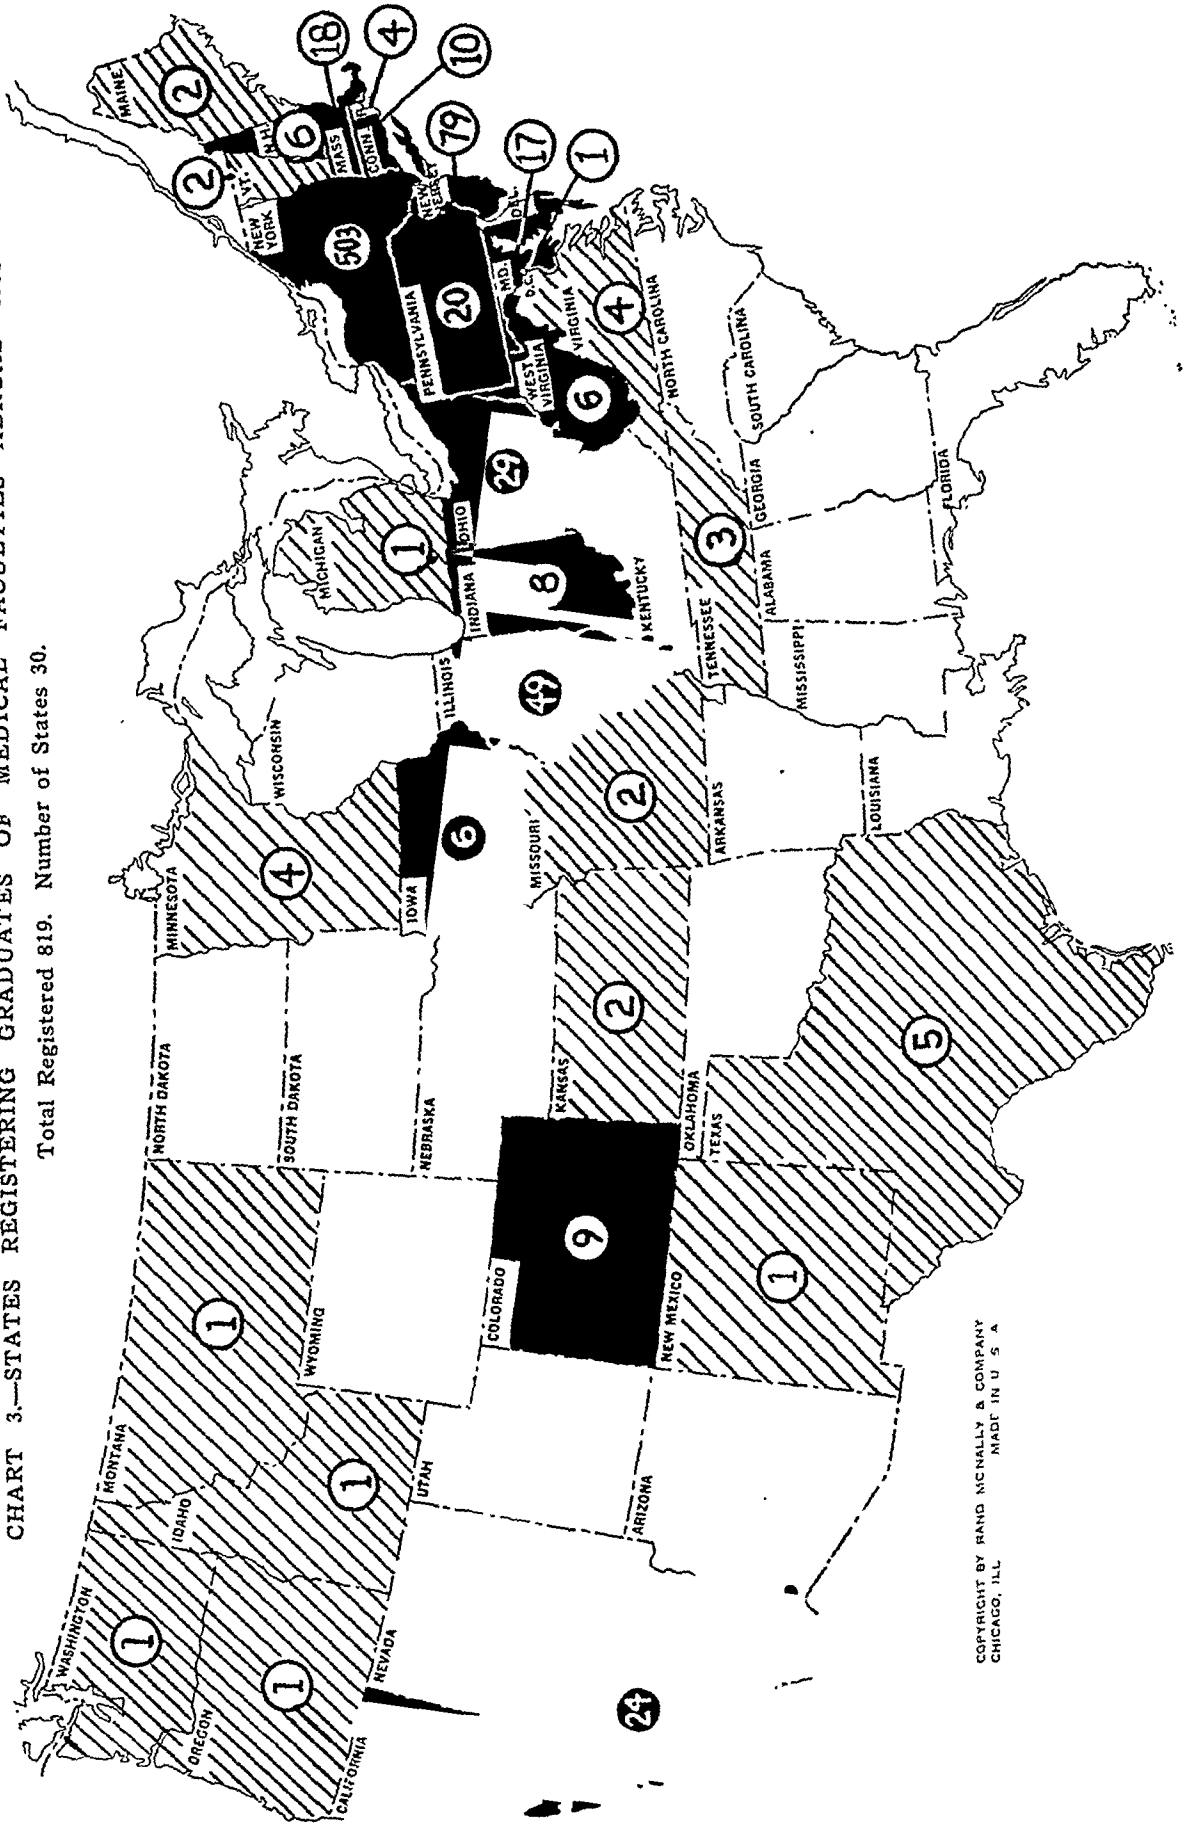

TABLE 17.—*Graduates of Unapproved Medical Schools Registered—1934-1938*

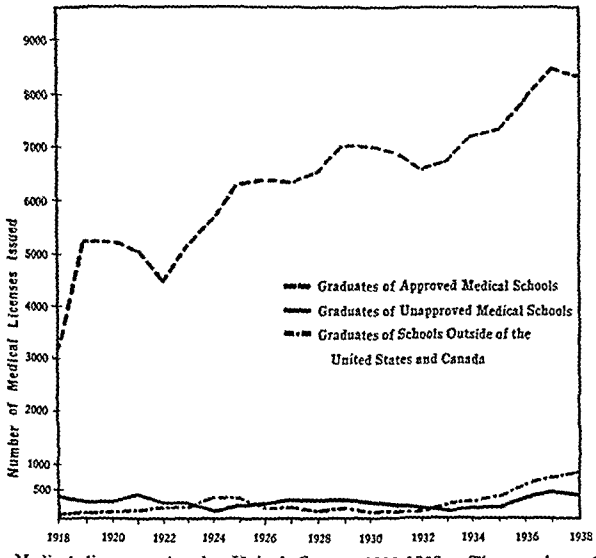
Totals	94	116	231	211	167	9	7	19	22	20	567

There was a decrease of twelve in the number registered by examination in 1938 and a larger decrease in the number registered by reciprocity or endorsement The graduating class of 1938 of medical schools in the United States was 183 fewer than that for 1937, which

CHART 3.—STATES REGISTERING GRADUATES OF MEDICAL FACULTIES ABROAD—1938

Total Registered 819. Number of States 30.

The states in black registered more than 5 such candidates, those shaded 5 or less.



was 5,377 and may account for the decrease. It may also be due to the fact that several of the states are proceeding with more caution in the licensure of graduates of foreign credentials exacting additional requirements, such as an internship or further training in a medical school in the United States, in order to test their fitness for the practice of medicine in this country. It was also anticipated that the number of those registered to practice medicine and surgery would decrease,

TABLE 18.—*Graduates of Schools of Osteopathy Registered by Medical Examining Boards—1934-1938*

as there has been a reduction in medical school enrolments in recent years. In seventy-seven schools in the United States there were 22,888 students enrolled in 1935, 22,564 in 1936, 22,095 in 1937 and 21,587 in 1938. Classes in subsequent years in many cases will be further reduced.

The percentage of failures in 1938 was 11.7, the highest percentage since 1924, when 11.8 per cent failed. This increase is largely the result of the failure of many

Medical licensure in the United States, 1918-1938. The number of medical licenses issued includes duplicate registration.

of the graduates of unapproved schools and osteopaths granted medical privileges to pass the test on the first try. This is further outlined in subsequent tables.

SOURCE OF PHYSICIANS REGISTERED

The educational fitness of the individuals registered in seventeen years, 1922-1938, is shown in table 16. Of the 9,527 registered by all methods in 1938, 8,300, or 87.1 per cent, graduated from approved medical schools and there were 1,227, 12.9 per cent, other practitioners registered. In the computation of these figures, all schools rated as class A and B by the Council on Medical Education and Hospitals since 1907 are classified as approved. In the column "Others" are included graduates of institutions prior to 1907 of foreign faculties of medicine, class C graduates, undergraduates, osteopaths and graduates of schools that have been refused all recognition as medical schools.

Of the 9,527 graduates registered in 1938, 6,582 were registered after examination and 2,945 by endorsement. There were 5,446 graduates of approved medical schools in the United States, 148 graduates of approved Canadian medical schools registered and 988 others. Likewise among those registered by endorsement there were 2,668 graduates of approved medical schools in the United States and forty-six graduates of approved medical schools in Canada and 231 others.

LICENSURE OF PHYSICIANS 1918-1938

In graphic form are here presented data regarding the licensure of physicians in twenty-one years. Three significant curves are shown; namely, graduates of approved medical schools, graduates of unapproved medical schools and graduates of foreign medical faculties. The number of approved graduates in the period shown has always been in the bracket above 3,000, while in the other groups it has until recent years been below 500. The number of unapproved graduates is gradually decreasing, although the number licensed with foreign credentials is increasing.

GRADUATES OF UNAPPROVED MEDICAL SCHOOLS REGISTERED

In table 17 will be noted the total number of graduates of those institutions which do not meet the standards for approval outlined by the House of Delegates of the American Medical Association who were registered with or without examination from 1934 to 1938.

Fourteen states registered 187 such graduates in 1938, 167 by examination and twenty without examination. The number decreased by forty-six the number registered in 1937. One each was licensed in Arizona, Kentucky, Missouri and Texas. One undergraduate was licensed in 1938 in New Jersey.

In the five year period shown, 866 graduates of unapproved schools and undergraduates were registered, 789 by examination and seventy-seven by reciprocity.

Chart 1, on page 1712, indicates by shaded lines those registering fewer than six graduates of unapproved medical schools and by a solid area those registering more than five such candidates during 1938.

MEDICAL EXAMINING BOARDS REGISTERING OSTEOPATHS TO PRACTICE MEDICINE, SURGERY OR BOTH

In table 18 are given the number of graduates of schools of osteopathy registered with or without examination by medical examining boards from 1934 to 1938 inclusive.

In 1938 ten states registered such individuals, 101 by examination and forty-three by endorsement of credentials. These osteopaths were registered in Colorado, the District of Columbia, Massachusetts, New Hampshire, New Jersey, Oregon, Texas, Virginia, Wisconsin and Wyoming and were granted the right to practice medicine, surgery or both by the board of medical examiners. These facts for 1938 are shown graphically in chart 2, on page 1714.

In the five year period 1934-1938, 545 graduates of osteopathic schools were registered in eleven states.

In Colorado osteopaths are admitted to the examination for a license to practice medicine. They have no

Compilation of data furnished by state examining boards. This information is not guaranteed as there may have been changes of which this office has not been advised. For an authentic statement write directly to the medical board.

* Refer to chart of "Reciprocity and Endorsement Policies" for further data

Reports from Arizona and New Jersey were not received

1. Certificate of National Board of Medical Examiners and licensure in country in which school of graduation is located
2. Internship or one year in medical school in United States.
3. Certificate of National Board of Medical Examiners
4. For graduates of last five years; if more than five years $50.
5. Residence of one year in Delaware
6. Provided similar privileges are accorded licentiates of District of Columbia by licensing agency of the jurisdiction from which the applicant comes
7. Senior year in Class A medical school in United States
8. Effective in May 1939
9. Reciprocity applicants only.
10. Application must be filed six months prior to date of examination
11. Licensed to practice medicine and surgery in country in which school of graduation is located
12. Diplomates of National Board of Medical Examiners eligible for licensure only.
13. At the discretion of the board.
14. Internship and one year graduate work.
15. After July 1, 1939
16. Applicants from schools in England and Scotland only

In most states all foreign credentials must be visaed by the American consul.

The Connecticut statute provides that any registered osteopath may practice either medicine, surgery or both, as the case may be, after passing a satisfactory examination before the medical examining board.

The Massachusetts statute, by definition, includes *osteopathy in the practice of medicine and does not* differentiate the type of license issued to an osteopathic applicant. The medical practice act requires that any applicant for license to practice must be in possession of a degree of doctor of medicine, or its equivalent, from a legally chartered medical school that gives a full four year course of instruction of not less than thirty-two weeks in each year.

In New Hampshire osteopaths are granted the right to practice medicine and surgery by the Board of Registration in Medicine.

Osteopaths who are duly registered and licensed to practice osteopathy in the state of New Jersey, who present three years of practice of surgery in a hospital approved by the Board of Medical Examiners, may be admitted to the examination to be licensed to practice medicine and surgery.

The statutes of Texas provide for the issuing of a license to practice medicine only. So far as the statutes indicate, the osteopaths are not restricted in their field of practice.

In the District of Columbia, Oregon, Virginia, Wisconsin and Wyoming, osteopaths are granted the right to practice surgery.

TABLE 21.—*Annual Registration*

Arkansas (Eclectic Board only)	Minnesota
California	Nebraska
Colorado	Nevada
Connecticut	New York
Florida	North Dakota
Georgia	Oregon
Idaho	Pennsylvania
Iowa	Texas
Kansas	Utah
Louisiana	Wyoming

Four states—Alabama, Delaware, Mississippi and North Carolina—require physicians to pay annually an occupational or commercial tax. The fee for this registration is generally $2

ANNUAL REGISTRATION

Twenty states, as shown in table 21, require that all physicians licensed register annually, whether or not they reside in the state.

PHYSICIANS EXAMINED ON THE BASIS OF CREDENTIALS OBTAINED IN COUNTRIES OTHER THAN UNITED STATES AND CANADA

An inquiry into the number of citizens of the United States studying medicine in faculties of medicine abroad has been carried on by the Council on Medical Education and Hospitals since 1931, when it became evident that great numbers were going to Europe to pursue medical courses. During the academic year 1937-1938, 1,346 citizens of the United States were enrolled in faculties of medicine abroad and 318 completed the medical course and have it is presumed returned to the United States to practice medicine. Similar figures obtain for other years. This influx of graduates from foreign medical schools has been a problem of major importance in the last few years from the point of view of hospital training, licensure and subsequent adjustment in the field of medical practice and is being further complicated by the migration to this country of physicians from central Europe.

Data recently received from state boards of medical licensure pertaining to the requirements of candidates for medical licensure holding credentials from medical schools outside the United States and Canada are presented in table 20. Reports were received from forty-six states and the District of Columbia. Eleven states report that, because of the inability to evaluate foreign credentials, holders of such certificates are not eligible for licensure. Of the remaining thirty-five states, twenty-nine require either United States citizenship

or first papers as a condition precedent to taking the state board examinations and fifteen of these states require full citizenship. In some states the requirement is made by rule of the medical board, in others the provision is by statute. In addition, other restrictions are imposed. Nine states require a certificate in the basic sciences. Twenty-two states require a one year internship in a United States hospital approved for intern training. In nine states there is a requirement of a senior year's work in an approved medical school in the United States. In three states the candidate must be in possession of the certificate of the National Board of Medical Examiners. Application for licensure must be on file six months prior to the date of examination in two states.

TABLE 23.—*Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930-1938*

Year	Number Examined	Passed	Percentage Failed
1930	167	92	44.9
1931	158	91	42.4
1932	182	96	47.3
1933	200	129	35.5
1934	285	170	40.2
1935	437	303	30.7
1936	588	382	35.0
1937	920	637	30.8
1938	1,166	716	38.6
Totals	4,103	2,616	36.3

Many of the foreign graduates are seeking or are serving internships in approved hospitals. In 1937 there were 245 employed in 105 hospitals throughout nineteen states. In 1938, 149 approved hospitals in twenty-nine states reported a total of 312. The Council has adopted the following resolution in an effort to assist hospitals in solving the perplexing problems associated with the selection of graduates from foreign schools:

Resolved, That, when suitable graduates of class A schools in the United States and Canada are not available, hospitals approved for intern training may accept graduates of European universities who have passed parts I and II of the examinations of the National Board of Medical Examiners.

Table 19 presents statistics covering physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards of the United States and by Hawaii and Puerto Rico in 1938. It is not known how many are citizens of the United States. The figures in the accompanying tabulations therefore represent both American and foreign born physicians educated abroad. Seventy-nine medical faculties, excluding seven licensing corporations, of eighteen European and five other countries were represented. There were 1,166 examined, of whom 716 passed and 450, 38.6 per cent, failed. Graduates of the University of Berlin (146) were examined in fourteen states, 37.0 per cent of whom failed. Twelve states examined students of the Universities of Vienna and Munich, and ten states graduates of the Universities of Heidelberg and Rome. All other schools were represented in less than ten states. Twenty-six states, Hawaii and Puerto Rico examined physicians educated abroad. The state of New York had the greatest number, 730, of whom 433 passed and 297, 40.7 per cent, failed. New Jersey examined 106, with sixty-six successful and forty unsuccessful results; 37.7 per cent failed. Illinois was third with fifty-five examined, forty-eight passed and seven, 12.7 per cent, failures.

In addition to the figures represented in this table, twenty-six graduates of foreign medical faculties were licensed in 1938 without examination by endorsement of their credentials. This is a considerable reduction over 1937. This is due in large part, as described in the text regarding reciprocity and endorsement candidates, to the decision of the New York Board of Regents, which state licenses the majority of such physicians, no longer to admit such applicants to licensure without examination.

Relative to the registration by the state of New York of graduates of the extramural schools in Great Britain, the New York State Education Department in January 1939 further directed that such registrations cease for all students hereafter admitted to these institutions and that the department no longer issue qualifying certificates to American students seeking admission to these schools. The department will continue to recognize, however, those already having received the qualifying certificate and already engaged in study in these schools. The schools referred to are the School of Medicine of the Royal Colleges, Edinburgh; Anderson College of Medicine, Glasgow; St. Mungo's College Medical School, Glasgow, and the Schools of Surgery, Royal College of Surgeons in Ireland, Dublin.

Chart 3, page 1716, shows in graphic form the states which during 1938 registered graduates of foreign medical faculties by examination, reciprocity and endorsement, or both. Included in the figures on the chart are those licenses granted by reciprocity and endorsement on the basis of a license obtained after examination from a medical board in this country. From a perusal of tables 2, 5 and 7 it can be ascertained how many were licensed by both these means in the various states. The states which licensed more than five graduates are indicated in black on the chart; those shaded, five or less. Fourteen states registered more than five, sixteen less than five. These thirty states altogether registered 819.

In table 22 are assembled figures showing the standing during the five year period 1933-1937 of the graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. Included also is a tabulation for the year 1938. One hundred and twenty-nine foreign faculties and ten of the licensing corporations of Great Britain were represented. During the five year period, 2,430 were examined and, in 1938, 1,166. The largest number from any one school in the five year period was the University of Vienna, 200, of whom 27.5 per cent failed. The University of Rome in the five year period was second, 188, of whom 49.5 per cent failed. There were 180 from the University of Berlin with 31.7 per cent failures.

Table 23, the last in this group of statistics, records the number of graduates of faculties of medicine abroad examined in the United States in nine years, 1930 to 1938 inclusive. There were 246 more examined in 1938 than in 1937 and 999 more than in 1930. During the nine year period, 4,103 were examined, of whom 2,616 passed and 36.3 per cent failed.

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. No opportunity is afforded for visiting and inspecting such schools, nor are official reports received from them. The Council therefore has no evidence on which to base a rating. A list of foreign schools which has been published from time to time merely serves as a key to the American Medical Directory and indicates the names of the institutions which physicians now licensed to practice in the United States attended or from which they graduated.

EXAMINING BOARDS IN MEDICAL SPECIALTIES

The House of Delegates of the American Medical Association at its annual session in 1933 passed the following resolution:

Resolved, That the Council on Medical Education and Hospitals is hereby authorized to express its approval of such examining boards in medical specialities as conform to the standards of administration formulated by the Council; and be it further

Resolved, That the Board of Trustees of the American Medical Association be urged to use the machinery of the American Medical Association, including the publication of its directory, in furthering the work of such examining boards as may be accredited by the Council.

Standards were formulated by the Council and approved by the House of Delegates, June 11-15, 1934. Thirteen boards have to date been approved, and those certified at the time of the publication of the fifteenth edition of the American Medical Directory are identified in the directory by the key A.B. 1, 2, and so on. The key number of the boards, the year incorporated and the number of certificates awarded to date appear in the following tabulation. The number certified by some of the boards has been reduced by death. Recorded therefore are the active diplomates.

Certificates Awarded by Examining Boards in Medical Specialties

Key A B	Name of Board	Year	Certificates Awarded (Active Diplomates)
1	American Board of Pediatrics	1933	1,335
2	American Board of Psychiatry and Neurology	1934	617
3	American Board of Orthopaedic Surgery	1934	578
4	American Board of Dermatology and Syphilology	1932	415
5	American Board of Radiology	1934	1,199
6	American Board of Urology	1935	553
7.	American Board of Obstetrics and Gynecology	1930	792
8	American Board of Internal Medicine	1935	1,703
9	American Board of Pathology	1936	689
10	American Board of Ophthalmology	1917	1,600
11	American Board of Otolaryngology	1924	2,807
12	American Board of Surgery	1937	1,039
13	American Board of Anesthesiology	1937	47
	Total		13,374

To date 13,374 have been certified in thirteen specialties. Each of these boards has published a booklet containing a brief statement regarding its organization personnel, purposes and qualifications for eligibility for certification, which is available on request to the officers of these boards or to the American Medical Association.

BASIC SCIENCE BOARDS

Boards for the examination in the basic sciences of all those desiring ultimately the right to practice the healing art functioned in eleven states and the District of Columbia in 1938, namely Arizona, Arkansas, Colorado, Connecticut, Iowa, Minnesota, Nebraska, Oklahoma, Oregon, Washington and Wisconsin. Basic science requirements were established in Michigan in 1937 but do not apply to any person matriculated in any medical, osteopathic or chiropractic school or college on or before Oct. 15, 1937. South Dakota enacted a basic science law in 1939 but it does not apply to students regularly registered and enrolled as of March 15, 1939, in schools of medicine, osteopathy and chiropractic. The years in which the various acts were enacted are shown in table 1.

Statistics based on the number of candidates certified in 1938 and those who failed to secure this certification, together with the totals for other years shown for comparison, are included in the accompanying tabulations. Similar data have been published in the State Board Number of THE JOURNAL since 1928.

The subjects in which examinations are conducted in the respective states and the District of Columbia are given in table 2. The subjects included in basic science examinations are specified by the statutes. The examination boards may neither add to nor subtract from such subjects. While the laws of some of these states include reciprocal agreements, the certificate is obtainable after examination in the majority of instances.

TABLE 1.—*States Having Basic Science Laws and Year of Enactment*

Arizona	1933	Minnesota	1927
Arkansas	1929	Nebraska	1927
Colorado	1937	Oklahoma	1937
Connecticut	1925	Oregon	1933
District of Columbia	1929	South Dakota	1939
Iowa	1933	Washington	1927
Michigan	1937	Wisconsin	1925

Applicants examined during 1938 in the various groups—physicians, osteopaths, chiropractors or students, and those unclassified—are included in table 3. The twelve boards functioning examined 1,325 candidates. Of this number, 1,168 were doctors of medicine, eighty-one osteopaths and thirty-two chiropractors; for forty-four it was not possible to determine what profession they represented. In applying for a basic science certificate it is not necessary in several of the states to mention the school of practice, but by checking the biographic records of the American Medical Association it has been possible to determine what profession the majority of the candidates represented. The remainder compose the unclassified group. Of all examined, 1,095 passed and 230 failed, 17.4 per cent. Of the physicians examined 12.2 per cent failed, of the osteopaths 42 per cent, of the chiropractors 75 per cent and of those unclassified 68.2 per cent. There were 1,026 physicians who passed, forty-seven osteopaths, eight chiropractors and fourteen unclassified. Minnesota examined the largest number, 266, of whom 21.1 per cent failed. The next largest number, 198, were examined in Wisconsin, with 8.1 per cent failures. Osteopaths were examined in Arizona, Arkansas, Colorado, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin: in fact, in every state except Oklahoma. Chiropractors were examined in Connecticut, Iowa, Minnesota,

TABLE 2.—*Subjects of Examinations*

persons who were unclassified. In addition there were 293 candidates certified without examination, by reciprocity or endorsement, consisting of 267 physicians, twenty-four osteopaths and two listed as unclassified. Iowa accepted the greatest number without examination, seventy, of whom sixty-nine were physicians and one was an osteopath. Minnesota registered sixty-three physicians and five osteopaths by this method. Wisconsin certified forty-two physicians, seven osteopaths and one unclassified, and Arkansas thirty-seven

physicians and six osteopaths. Arizona, Connecticut and Washington licensed none without examination. Arizona, and Washington, by law, have no reciprocal agreements. No chiropractors were licensed without examination but two in the unclassified group were certified by this method.

The number of candidates examined, or certified by reciprocity or endorsement, from 1927 to 1938 inclusive will be found in table 5. In 1928, when five boards were functioning, there were 646 physicians examined, of whom sixty, or 9.3 per cent, failed and fifty-nine other practitioners, of whom twenty-eight, or 47.5 per cent, failed. In 1938, 1,293 physicians and ninety-five other practitioners were certified. During the twelve year period a total of 9,370 physicians were examined, of whom 1,122, 12.0 per cent, failed and 931 other practitioners, of whom 507, 54.5 per cent, failed. During this period 1,532 physicians were certified without examination, while only ninety-one other practitioners were so registered.

Altogether, 10,295 certificates have been issued by basic science boards since 1927, of whom 9,780 were granted to physicians and 515 to other practitioners. From the high percentage of failures in the other practitioner group it seems apparent that the enforcement

of basic science laws affects most seriously this group. The object of these boards has been to provide a means of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art. Basic science bills are being advocated in several states and bills are pending in the legislature.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners was organized in 1915 and chartered March 17, 1922, under the laws of the District of Columbia. Its purpose was to establish in this country a qualifying examination of such character that successful candidates could be admitted to the practice of medicine by state boards of medical licensure. Its constitution provides for a membership of thirty. This includes six members representing the federal services, five members nominated by the Federation of State Medical Boards of the United States, three members nominated by the Association of American Medical Colleges, two members nominated by the Council on Medical Education and Hospitals of the American Medical Association, and fourteen members elected at large.

Statistics are herewith presented regarding the examinations of and the issuance of certificates by the National Board of Medical Examiners. Similar material has been presented in the State Board Number of THE JOURNAL for twenty-one years.

Up to Dec. 31, 1921, eleven examinations were held as shown in table 1.

Since 1922 the examination has been given in three parts, parts I and II being written examinations and part III a practical and clinical examination. The data included in the following paragraphs refer to the examination and the issuance of certificates to this group and

TABLE 1.—*Examinations—1916-1921*

arranged for candidates taking part I at the end of their second medical year in schools in which the third year curriculums include courses in one or two subjects of this part. The subjects thus postponed may be taken at any examination period after the candidate has completed them in his medical school. Any candidate not entitled to take an incomplete examination in part I may, if he so elects, take a divided examination by writing any four subjects at one time and the remaining two within thirteen months, but after at least one semester of study. Incomplete examinations were not included when percentages were being computed, since they represent neither a candidate eligible for certification nor a failure.

A candidate who fails to make an average of 75 per cent but has received grades of at least 75 per cent in three or more main divisions is required to repeat those divisions, either in whole or in part, in which he received grades below 75 per cent. Grades below 60 per cent in any of the subdivisions are not acceptable if the grade for the corresponding main division is under 75 per cent. In such cases the candidate is "referred" in this subdivision and required after a three months interval to pass a reexamination. The privilege of a second reexamination is determined in each case by the board "Referred" candidates are likewise excluded from the statistics.

Four examinations in part I were held in 1938, as indicated in table 2 Altogether 1,653 examinations were given, 985 passed, 508 were given incomplete examinations and 160, or 14.0 per cent, failed.

Totals	9,118	8,249	36	833	9 2

Four examinations were also given in part II, figures for which appear in table 3 During 1938, 861 were so examined, of whom 815 passed and forty-six, 5 3 per cent, failed.

Since 1922 a total of 17,375 examinations have been given in part I and 9,118 in part II. From 1922 to 1938 inclusive, 11,016 individuals were successful in passing part I and 8,249 in passing part II. The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and also some who pass parts I and II in the same year. Therefore they represent examinations conducted rather than individuals examined. In the seventeen year period since 1922 there have been 1,780 failures in part I, 13.9 per cent, and 833 in part II, 9.2 per cent.

Between 1916 and 1921 a total of 325 were examined, of whom 268 passed and 57, 14 3 per cent, failed Total certificates awarded, 6 708

* Excluding "referred" examinations

The results of examinations in part III for the seventeen year period 1922 to 1938 inclusive are represented in table 4. In 1938, 706 were examined, as compared with only twenty-two in 1922. Of the number examined in 1938, twenty-four, or 3.4 per cent, failed. The highest percentage of failures was in 1927, when 293 were examined and twenty-one, 7.2 per cent, failed. In seventeen years 6,744 were examined, of whom 6,440 were granted certificates and 304, 4.5 per cent, failed. Here again a candidate having failed may subsequently receive a certificate.

From 1916 to 1921, when the examination was not given in three parts, 325 were examined, of whom 268 passed and fifty-seven, 14.3 per cent, failed.

Altogether from 1916 up to and including 1938, 6,708 certificates have been granted.

The number of persons examined during any one year is given in table 5. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1938 a candidate passed part I but later failed part II, he is listed as having failed. Taking this into consideration, there were 2,990 who took at least one of the examinations of the National Board of Medical Examiners during 1938, as compared with 525 in 1922. A total of 30,759 were examined in one or more of the examinations in the seventeen years shown, of whom 23,817 passed, 2,561 failed, 4,381 took incomplete examinations and 9.7 per cent failed.

* Excluding "referred" examinations.

Examinations in part III were held during 1938, at which 682 were successful. Graduates of fifty-nine approved schools in the United States and four in Canada were examined. Thirteen graduates of medical faculties abroad were also certified. Table 6 records the number of diplomates from each school certified in 1938 in part III. At the College of Medical Evangelists students are required to pass parts I and II as a prerequisite to receiving their diploma. The comprehensive qualifying examination, or part I of the examination of the National Board, is required of all medical students entering Yale University School of Medicine in the fall of 1937. Students at Georgetown University School of Medicine are urged to take the examinations of the National Board. Students admitted to Boston University School of Medicine subsequent to 1937 are required to pass part I in order to supplement the qualifications for promotion to the third year class. All students before entering the senior class at the New York Medical College must have taken part I of the examination of the National Board. While the certificate is not required by these schools, their graduates and, in addition, those of Harvard, Tufts and Duke University represented the majority of those certified.

Diplomates licensed on the basis of their credentials have increased from two in 1917 to 673 in 1938, 4,793 having been so licensed since the National Board was formed. However, 6,708 have received the certificate of the board. In 1938 diplomates were registered on the basis of credentials in thirty-eight states, the District of Columbia, Alaska, Hawaii and Puerto Rico.

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of forty-four states and Alaska, Canal Zone, Hawaii and Puerto Rico (table 7).

TABLE 7.—*States Endorsing Certificates of National Board of Medical Examiners*

Alabama	Illinois	Montana	Pennsylvania
Alaska	Indiana	Nebraska	Puerto Rico
Arizona	Iowa	Nevada	Rhode Island
Arkansas	Kansas	New Hampshire	South Carolina
California	Kentucky	New Jersey	South Dakota
Canal Zone	Maine	New Mexico	Tennessee
Colorado	Maryland	New York	Utah
Connecticut	Massachusetts	North Carolina	Vermont
Delaware	Michigan	North Dakota	Virginia
Dist. of Columbia	Minnesota	Ohio	Washington
Georgia	Mississippi	Oklahoma	West Virginia
Hawaii	Missouri	Oregon	Wyoming

Some of these boards have additional requirements.

Diplomates of the National Board of Medical Examiners are admitted to the final examination given by the Conjoint Examining Board of England and Ireland and the Triple Qualification Board of Scotland. The certificate is accepted by the United States Army for admission to its Medical Corps and also by the United States Public Health Service and is recognized also in Lebanon, South Africa, Spain and Turkey.

Examinations in parts I and II are held at class A medical schools where there are five or more candidates desiring to be examined, and part III is held in twenty-two established centers throughout the United States.

SATURDAY, APRIL 29, 1939

OBITUARIES OF PHYSICIANS PUBLISHED IN 1938

The number of obituaries of physicians published in THE JOURNAL during 1938 was 3,768, including 3,630 of the United States as compared with 3,277 in 1937, also 138 of Canadian physicians. Four died in the Philippine Islands, 3 each in Mexico and Puerto Rico, 2 each in Cuba and France, and 1 each in Africa, the Canal Zone, England, India and Korea. The obituaries of 108 women physicians were published, as compared with 113 in 1937. The number of graduates of medical schools in the United States for the fiscal year ended June 30, 1938, was 5,194. Deducting the number of physicians whose obituaries were published, there was a net addition to the profession for the year of 1,564, not including physicians coming to the United States from abroad.

Ages.—The average age at death of those classified as of the United States was 65.6, as compared with 65.4 in 1937. Thirty-two physicians died between the ages of 25 and 29, fifty-two between 30 and 34, seventy-three between 35 and 39, eighty-one between 40 and 44, 158 between 45 and 49, 250 between 50 and 54, 403 between 55 and 59, 524 between 60 and 64, 590 between 65 and 69, 535 between 70 and 74, 421 between 75 and 79, 312 between 80 and 84, 144 between 85 and 89, forty-three for 90 and eight for 95 and over. In four cases the age was not determined.

Causes of Death.—Heart disease was again the leading cause of death, as it has been for many years. Some contributory causes are also included in THE JOURNAL'S tabulation as they have been in former years. For example, when a report of the cause of death gave chronic nephritis and heart disease, it was published as such in THE JOURNAL and was reported on the statistical charts under both diseases. Thus heart disease was reported as a cause of death in 1,491 cases. Endocarditis or myocarditis was specified in 396 cases, coronary thrombosis in 337, coronary occlusion in 167 and angina pectoris in 84. Other diseases of the heart caused 507 deaths. Arteriosclerosis was the second most frequent cause, with 442. Cerebral hemorrhage was the third most frequent cause with 384 deaths; 28 additional deaths were reported as due to paralysis. Fourth on the list was pneumonia with 350 deaths, of which 111 were specified as bronchopneumonia. Of 334 deaths reported as due to cancer, the stomach and liver were reported affected in 66 cases, the prostate gland in 51, the intestine in 42, the female genital organs in 5; in 180 cases the part affected was not specified. Nephritis was reported as the cause of 204 deaths. The number of cases in which hypertension was reported was 125, embolism and thrombosis exclusive of coronary thrombosis 124, uremia 99, other diseases of the urinary system 73, diabetes 77, tuberculosis 70, other diseases of the respiratory system 5, diseases of the prostate other than cancer 54, cirrhosis of the liver 44, other diseases of the liver 11, senility 33, ulcer of the stomach and duodenum 29, other diseases of the digestive system 22, septicemia 28, peritonitis 24, influenza 23, leukemia and intestinal obstruction 22 each, appendicitis 18, pernicious anemia 17, cholecystitis 16, encephalitis and paralysis agitans 15 each, arthritis 14, biliary calculi and chronic bronchitis 13 each, hemorrhage 12, meningitis and gangrene 11 each, brain tumor 10, other tumors 4, hernia 9, abscesses 8, Hodgkin's disease, aplastic anemia and aneurysm 7 each, asthma 6, diseases of the veins and typhoid 5 each, cerebral sclerosis, empyema, osteomyelitis, shock and streptococcic infection 4 each, carbuncle, diverticulitis, malaria, obstructive jaundice, pleurisy and streptococcic infection of the throat 3 each, Addison's disease, Adams-Stokes syndrome, amyotrophic lateral sclerosis, bacillary dysentery, cerebral softening, diverticulosis, esophageal varix, granulocytopenia, dementia paralytica, heat prostration, multiple sclerosis, myelitis, sinusitis, pyloric stenosis, ruptured gallbladder, tonsillitis, undulant fever and secondary anemia 2 each. Other diseases causing one death each as reported were abscessed teeth, actinomycosis, alcoholism, amebic dysentery, asphyxiation caused by deformity of the spine, calcification of the pineal gland, cellulitis, cerebral anemia, diphtheria, disease of the adrenal glands, duodenal perforation, erysipelas, food poisoning, furunculosis, gas bacillus infection, ileitis, laryngospasm, Ludwig's angina, lymphoma, mastoiditis, mediastinitis, multiple myeloma, multiple neuritis, occlusion of the popliteal artery, otitis media, paraldehyde poisoning, paralytic ileus, parotitis, pellagra, persistent thymus, pulmonary fibrosis, purpura haemorrhagica, respiratory failure, rupture of the aorta, rupture of the heart, spinal sclerosis, splenitis, sponta-

neous pneumothorax, subarachnoid hemorrhage, teratoma, tetanus, thyroid disease, toxic purpura, tularemia, varicose ulcer and vesical calculi.

Accidental Deaths.—One hundred and fifty-five physicians died as the result of accidents in 1938, compared with 151 in the previous year. Automobile accidents accounted for 81 deaths, falls 30, drowning 9, burns 7, airplane accidents 4, carbon monoxide gas 3, illuminating gas 2, shooting 2, explosions, overdose of medicine, poison, street car and train accidents 1 each. In 8 cases unexplained fractures were given as causes of death. One physician died of injuries received when he was struck by a motorcycle, one of an accidental wound from a hypodermic needle and one from the bite of an insect.

Suicides and Homicides.—Suicide was the cause of eighty-one deaths of physicians in 1938. Bullet wounds accounted for 31 of these deaths, carbon monoxide poisoning 9, overdoses of medicine 7, jumping 6, incised wounds 6, gas and hanging 5 each, poison 4, stabbing 2, burns 1. One physician jumped in front of a train. In five cases the method was not reported; in addition four deaths from the following causes could not be classified because of insufficient information: falls from window 2, carbon monoxide poisoning 1, shooting 1. There were six homicides.

Civil Positions.—Among the decedents were 206 physicians who were or had been teachers in medical schools, 466 who had served in the World War, 13 veterans of the Civil War and 70 veterans of the Spanish-American War. One hundred and eighty-one were or had been health officers, 151 members of boards of education, 72 members of boards of health and 21 members of state boards of medical examiners. There were 75 who were or had been coroners, 51 mayors, 39 members of state legislatures, 32 authors, 26 bank presidents, 15 pharmacists, 15 members of city councils, 12 editors, 10 postmasters, 10 police surgeons, 8 dentists, 7 missionaries, 5 clergymen, 4 lawyers, 2 justices of the peace, 1 United States Senator, 1 Congressman and 1 judge. There were 21 members of the United States Army Medical Corps, 12 of the United States Navy Medical Corps, 13 of the United States Public Health Service, 13 of the Veterans' Administration and 5 of the Indian Medical Service.

Association Officers.—Among those who died who were or had been officers of the American Medical Association were 2 vice presidents and 6 section officers. Twenty members or former members of the House of Delegates died during the year. There were also 25 presidents or former presidents of state medical associations and 2 secretaries.

MEDICAL EDUCATION IN THE UNITED STATES AND ABROAD

Elsewhere in this issue are presented the figures reported by the medical examining boards of the United States. Since, for a variety of reasons, an unusually large number of applicants have come from other countries, an opportunity is afforded to compare the success before examining boards of those whose professional education has been received in approved schools in the United States with corresponding figures for those educated abroad. Reports to the Council do not distinguish between citizens of this country who, having gone elsewhere to study medicine, return here to practice, and natives of other countries who apply here for a medical license.

As a comparatively small number of physicians from some countries have taken the licensing examinations, only those countries are included from which more than twenty-five candidates were examined during 1938.

Since the number of failures among graduates of approved schools was only 3.0 per cent, it is obvious that candidates admitted to state board examinations on the basis of foreign credentials are not as well prepared for the licensing test as those who have been educated in our own schools. It may be objected that the poor record of graduates of foreign schools is due to the fact that they have not yet mastered the English language. This explanation, however, can account only partially for the discrepancy, since many of those educated abroad were born and raised in this country.

Failures of Candidates from Abroad

	Number Examined	Percentage of Failures
Austria	136	28.7
France	43	37.2
Germany	505	41.0
Italy	165	53.9
Scotland	76	17.1
Switzerland	172	32.6
	1,097	38.3

WHAT IS OSTEOPATHY?

Is it medicine or is it not? Do schools of osteopathy teach medicine or do they not? Last year 144 applicants whose training had been received in osteopathic schools were licensed by the boards of medical examiners in ten states to practice medicine, surgery or both; 101 were licensed after examination and forty-three without examination. The numbers licensed in each of these ten states are shown in chart 2, on page 1714.

In a number of states bills have been introduced which, if passed, would give to graduates of osteopathic schools the same privileges and responsibilities that are given to graduates of approved medical schools. Is such legislation compatible with public safety or in the interest of public welfare? Proponents of these measures claim that medicine is taught as completely and as thoroughly in schools of osteopathy as in schools of medicine.

Osteopathic schools have consistently refused to permit an inspection by the Council on Medical Education and Hospitals of the American Medical Association. Recently, however, a committee of the Kansas legislature visited one of these schools and found conditions which a recognized medical school would not tolerate. In the medical sciences, anatomy, biochemistry, physiology, bacteriology and pathology the faculty was utterly inadequate both in numbers and in scientific training. For teaching the various clinical branches of medicine the number of hospital patients available was about one twenty-fifth of the number to which students at the University of Kansas have access. This school of osteopathy, at least, does not even remotely approach the generally accepted standards of education for the practice of medicine.

Current Comment

PHENYLPYRUVICA OLIGOPHRENIA

A mental condition known as phenylpyruvica oligophrenia, or imbecillitas phenylpyruvica, has recently been described by investigators in Norway,[1] England[2] and the United States.[3] Mentally defective patients suffering from phenylpyruvica oligophrenia characteristically excrete phenylpyruvic acid in the urine, being apparently unable to oxidize and decarboxylate phenylpyruvic acid in a normal manner. The formation of phenylpyruvic acid in the body is thought to result from the oxidative deamination of the essential amino acid phenylalanine. When phenylalanine is fed to persons with this metabolic abnormality, the excretion of phenylpyruvic acid in the urine is increased. The disease is therefore characterized biochemically by the inhibition of the metabolism of phenylalanine at the stage of phenylpyruvic acid. In this connection it is noteworthy that Peters and his collaborators in England have found that the oxidation and decarboxylation of pyruvic acid in certain tissues require the presence of thiamin (vitamin B_1). Thiamin apparently serves as a precursor of cocarboxylase, the latter being thiamin pyrophosphate, and it has been reported that in many tissues a dynamic equilibrium exists between free thiamin and its pyrophosphoric acid ester. Several years ago it was established that cocarboxylase is a coenzyme necessary for the decarboxylation of pyruvic acid in certain enzyme systems. The observation of Closs and Folling that white rats on a vitamin B_1 deficient diet excrete phenylpyruvic acid when large amounts of phenylalanine are ingested and that control animals receiving thiamin chloride do not excrete phenylpyruvic acid under the same conditions is relevant. These clinical and experimental observations may be expected to stimulate further work designed to elucidate the possible relationship existing between thiamin and cocarboxylase on the one hand and the metabolic disturbance phenylpyruvica oligophrenia on the other.

A MEDICAL SOCIETY AND CONTAGIOUS DISEASE

While the interest of organized medicine in the public health is a matter of long record, recognition of that interest is rare. The part played by the Chicago Medical Society in the control of contagious disease is one of the principal aspects of a richly documented manuscript by Miss Webb[1] of the University of Chicago. Many entries in the minutes of the Chicago Medical Society from its formation in the fall of 1850 attest its activity both as a society and by many of its individual members in attempting to arouse the community to concerted and effective action in the control of contagious diseases. Although a city board of health existed for most of the period preceding the fire, Miss Webb obtained no evidence that it had even met in some years. The medical society demonstrated a constant interest in and activity for the best public health measures, as, for example, sound registration of vital statistics. In fact, Chicago's mortality records were apparently most inaccurate until 1868, the improvement at that time being the direct result of a petition of the Chicago Medical Society to the city council in 1866. "Through the years," Miss Webb states, "the only really sustained fight [for adequate protection against contagious disease] came from the medical profession, whose members realized the basic needs and urged reform." In commenting further on this matter she stated that while individual physicians had for a long time taken part in civic questions they naturally became more effective as members of an organized group.

INCREASING IMPORTATION OF PAPAIN

Papain is an enzyme of the proteolytic group, changing native proteins, proteoses and peptones to amino acids. The activity of papain is greatly increased by hydrocyanic acid, by hydrogen sulfide and by glutathione. It acts in an acid medium (p_H 4 to 7) and at temperatures of from 65 to 90 C. The papain of commerce is obtained from the melon tree (Carica papaya), which flourishes in tropical and subtropical regions and is obtained in the form of latex, the dried milky juice of the unripe papaya fruit. Of late, papain has been finding its greatest use in preparing "tenderized" meat. Import statistics[1] show a fourfold increase in recent years; 54,000 pounds valued at $50,000 was imported in 1932, whereas the amount in 1938 was 223,000 pounds of crude papain valued at $329,000. Ceylon is the largest exporter of papain to the United States, in 1938 sending 173,000 pounds; 36,000 pounds came from elsewhere in the United Kingdom with Japan, Siam and New Zealand contributing smaller quantities. Long recognized as a powerful proteolytic ferment, papain, which in several respects is an abnormal enzyme, seems now to be making a definite contribution to the enhancement of the esthetic side of our national dietary. Its usefulness as a therapeutic agent, however, is not recognized.

ORGANIZATION SECTION

"ECONOMICAL ADMINISTRATION OF HEALTH INSURANCE BENEFITS"

Nothing more illustrative of the dominance of financial considerations over medical science in the administration of sickness insurance has appeared than this report of the International Labour Office.[1] Like most of the publications of this office, it is the result of the work of several commissions of experts. The material has been finally arranged by Walter Pryll, social medical officer of the International Labour Office and for many years active in the administration of sickness insurance institutions in Germany. This domination of financial considerations and the economy which it enforces cannot well be criticized once the system of sickness insurance comes into existence, but its very necessity involves such restrictions on the development of medical science and its application to the large section of the population covered by insurance as to constitute in itself an indictment of the entire principle of sickness insurance.

"Social insurance institutions must base themselves on the principle of economy and, as far as possible, make it govern all their organization and working" (p. 10). "The funds are therefore compelled to strike the best balance they can between the special needs of those insured with them and the limited means at their disposal" (p. 13). Such a program must restrict the application of many types of medical care, although the funds are required to use "all the means and methods that have been approved by science and tested in practice, in so far as they are easily available at a reasonable cost" (p. 16).

We are told that "it was the principle of economy that led the insurance institutions to engage in preventive work" and that "prevention is not only easier but also cheaper than cure and than the cost of compensation" (p. 16). No illustrations are offered, however, of the extent of such preventive work under insurance or of the results it has produced, and just a little later it is admitted that the funds "must not use any of their resources for the individual or collective prevention of disease if this form of activity is not expressly prescribed or permitted by law" (p. 19).

In spite of many cleverly worded explanations intended to show that this economical administration does not injure the practice of medicine, any one accustomed to the professional attitude in a country free from insurance institutions who reads the multitude of restrictions cannot fail to be impressed with the fact that the one dominating thought that must constantly be in the physician's mind is not the welfare of the patient but the welfare of the insurance funds.

Advocates of sickness insurance in the United States who visualize great clinics of specialists using highly expensive equipment might read with profit the statement that "it is sheer extravagance to have a patient very thoroughly examined by a specialist, with the aid of the most expensive apparatus available, before considering whether such a step is necessary or likely to be fruitful, so that in the end such additional knowledge as may be obtained is bought at too great an expenditure of material, time, and money" (p. 35). In no country do insured patients customarily receive any such service.

There is an entire chapter on the application of the principle of economy to diagnosis, which alternates between emphasis on the necessity of careful diagnosis to detect incipient diseases and numerous instances of the economic obstacles which insurance must maintain that would prevent any such diagnosis. The ideal is set up not only of the diagnosis of the disease but of the "psychophysical state of the patient," of his relations to society, and of the "prognosis and plan of treatment and cure." The reader who knew nothing of insurance might think that such a diagnosis was common under insurance, but the compiler of this volume wisely does not attempt to give any examples.

When it comes to the application of the principle of economy to therapeutics, we are told that "the private practitioner may apply any methods of diagnosis and treatment which he considers necessary so far as his patient is prepared to pay the cost, whereas a practitioner who is treating insured persons must follow the principle of economy . . ." (p. 64). We are assured that "the patient must not be required to put up with second-rate methods of treatment or with cheap measures of inferior quality selected merely on grounds of economy" but that "the necessary treatment is that which alone of all the appropriate, adequate and reasonably priced methods guarantees success and is applied only so far as is necessary to achieve the purpose of the insurance scheme" (p. 72). The assumption that the "necessary treatment" which "guarantees success" can be determined would seem to require that the insurance physician have a knowledge that exceeds medical science. The point is repeatedly emphasized that in many cases rest, massage, baths or other treatment not requiring drugs or appliances may be used for reasons of economy. Perhaps this explains the renaissance of the "naturheiler" and other cults and quacks in Germany under Hitler. The physician is constantly warned against the overuse of drugs. No complaint could be made against such a warning if really based on therapeutic reasons, but the constant emphasis on economy suggests that wholly different reasons actually govern. This is true of the recommendation that only drugs included in the special formularies be used and that proprietaries be avoided. But on this point also the emphasis on the economy angle is far greater than on the scientific.

That politics even more than economy may guide the actions of the legislators is indicated by the following, which is perhaps the most significant statement in the entire report:

"Nor can the legislative authorities be guided solely by economic considerations when drawing up the regulations concerning benefits. Financial limits may be imposed, beyond which they cannot go. They may have to reject many ideas that are acceptable from the point of view of economy and agree to others that are economically unsound simply because of the relative strength of the various political parties in the government at the time" (p. 19).

There is an entire chapter on the application of the principle of economy to preventive measures, but no mention is made of immunization, and it would appear that most of these measures would consist of good advice and cooperation with health departments and special institutions for controlling such diseases as tuberculosis.

One large section is devoted to a discussion of the principle of economy in national laws and regulations. Once more it is difficult to raise a direct objection to most of these regulations, but when they are examined as a whole they give the picture of a legal cage within which the physician is compelled to practice. He is constantly warned to watch the quantity prescribed, to see that containers are returned and used again, that only certain types of prescriptions that require the least time to compound are used, and so on.

One source of economy is never mentioned. There is no discussion of the costs of administration, of the palatial offices of insurance carriers—always so much better equipped than the hospitals—or of the swarm of administrators whose expenses must be met out of the certainly inadequate income derived from poorly paid workers.

More than half the book is devoted to the national laws and regulations designed to enforce the principle of economy in Czechoslovakia, France, Germany, Great Britain, Hungary, Poland and Yugoslavia. These laws and regulations, with their provisions for the supervision of insurance practitioners and

1. Economical Administration of Health Insurance Benefits, Studies and Reports, Series M (Social Insurance) No. 15, International Labour Office, Geneva, 1938.

control of excessive treatment and prescribing, are a complete answer to those who say that there is no restriction by lay authorities of the practice of medicine under insurance. Nearly every country provides for elaborate pricing and statistical compilation of the cost of prescriptions to establish a median or average cost for each prescription. Any physician who exceeds this cost in any considerable manner is warned and, if he does not conform, is punished. Governments and insurance carriers maintain extensive and costly systems of supervising physicians and "sick visitors" to check the work of the insurance physician and to see that he does not spend too much in treatment. Everywhere the emphasis is on cost rather than on quality of medical care.

The effect of all this on a physician cannot but be to compel him to keep constantly in the forefront of his mind not the principles of the best medical diagnosis and treatment but the "principle of economy." He knows that his professional reputation and livelihood will be destroyed if he oversteps the economy principles much more quickly than if he violates the principles of proper diagnosis and adequate treatment.

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 o'clock mountain time, 11 a. m. Pacific time).

Starting April 30, daylight saving time takes effect in Chicago. The program will therefore be broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there will be no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening, on and after May 1 (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

May 3. Healthier Mothers.
May 10. The Doctor's Workshop.
May 17. Healthier Babies.

THE ST. LOUIS SESSION

Dinner to Women Physicians

A Library Dinner will be given Monday, May 15, at 6:30 p. m. in the Tower Room at the Congress Hotel, St. Louis, at which the visiting women physicians will be the guests of the Committee on Women Physicians of the Local Committee on Arrangements, members of which will act as hostesses. Dr. Bertha Van Hoosen, Chicago, will be chairman.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 835 has passed the Senate, providing compensation for disability or death resulting from injury to employees of contractors on public buildings and public works. S. 1265 and S. 2203 have been reported to the Senate, proposing among other things to add a new title to the Social Security Act whereunder an appropriation of $125,000,000 is authorized for the fiscal year ending June 30, 1941, and thereafter for each fiscal year such sum as may be necessary to enable the states to furnish financial assistance to needy handicapped individuals, defined to mean individuals not eligible for assistance through state plans approved under the titles of the Social Security Act providing for old-age assistance, aid to dependent children and aid to the blind, and who, by reason of physical or mental disability other than disability arising out of impairment of vision, are unable to perform substantial gainful employment. S. 1540 has passed the Senate, proposing to adjust the compensation of the members of the National Advisory Health Council not in the regular employment of the government. S. 1899 has passed the Senate, providing for the detail of a commissioned medical officer of the United States Public Health Service to serve as Assistant to the Surgeon General. H. R. 1776 has passed the Senate, providing for the assignment of medical officers of the United States Public Health Service for duty on vessels of the Coast and Geodetic Survey. H. R. 2296 has passed the House, proposing to restore certain benefits to World War veterans suffering from paralysis, paresis or blindness, or who are helpless or bedridden. H. R. 2320 has passed the House, providing domiciliary care, medical and hospital treatment and burial benefits to certain veterans of the Spanish-American War, the Philippine Insurrection and the Boxer Rebellion. H. R. 2987 has been reported to the House, with recommendation that it pass, proposing to authorize the Veterans' Administration to make payments to nonmilitary employees who donate blood for transfusions for veterans hospitalized in veterans' hospital facilities. H. R. 3537 has passed the Senate, with amendments, to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States. H. R. 5379 was defeated in the House April 20 by a vote of 234 to 118, proposing to exempt Dr. Nathan Tucker's Asthma Specific from certain labeling requirements of the Federal Food, Drug and Cosmetic Act. H. R. 5762, introduced by Representative Lea, California, has passed the House, with amendment, proposing, among other things, to postpone from June 25, 1939, to Jan. 1, 1940, the effective date of certain of the provisions of the Federal Food, Drug and Cosmetic Act that have not already gone into effect, relating principally to labeling requirements for foods, drugs, devices and cosmetics and the use of coal-tar dyes in foods, drugs and cosmetics. The bill proposes also to authorize the Secretary of Agriculture to postpone, but not beyond July 1, 1940, the effective date of certain labeling requirements of the act so far as they may be applicable to labeling which was lithographed, etched, stamped, printed or otherwise manufactured prior to Feb. 1, 1939, and which would have complied with the Food and Drugs Act of 1906, as amended. The bill also proposes to amend section 502(d) of the Federal Food, Drug and Cosmetic Act so as to require the labels of drugs containing any narcotic or hypnotic substances to state only the "name and quantity or proportion" rather than the "name, quantity, and percentage" of such substances.

Bills Introduced.—H. R. 5691, introduced by Representative Sutphin, New Jersey, proposes to amend the Federal Emergency Relief Act of 1933 for continuation of the civil works program by eliminating the requirement that an injury sustained by an employee must be of traumatic origin to entitle the employee to compensation, including medical and hospital benefits. H. R. 5841, introduced by Representative Patrick, Alabama, proposes to amend the Social Security Act by adding a new title thereto under which an appropriation of $1,000,000 will be authorized for the fiscal year ending July 1, 1940, and thereafter such sum as may be necessary, to enable the states to aid in restoration of sight to the blind by furnishing hospitalization and medical and surgical aid. H. R. 5870, introduced by Representative Angell, Oregon, proposes to authorize such federal sums as

may be necessary to pay an annuity at a rate not to exceed $50 a month to blind persons whose annual income from sources other than annuities payable under the act is less than $1,200. *H. R. 5874*, introduced by Representative McKeough, Illinois, proposes to include the name of Gustaf E. Lambert among those honored by an act recognizing the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever. H. R. 5884, introduced by Representative Vinson, Georgia, proposes to authorize the President to appoint for temporary service in the Navy 100 acting assistant surgeons, who shall have the rank and compensation of assistant surgeons.

STATE MEDICAL LEGISLATION

California

Bill Introduced.—A. 2795 proposes to prohibit the distribution of serums, vaccines, bacterial cultures and viruses produced other than in a laboratory licensed either by the Department of Health, the United States Public Health Service or the Bureau of Animal Industry of the United States Department of Agriculture. The bill proposes to repeal the law approved June 1, 1935, regulating the production and distribution of serums, vaccines, bacterial cultures and viruses.

Florida

Bills Introduced.—S. 149 and H. 74 propose to authorize the formation of corporations to operate nonprofit service plans whereby hospital care may be provided by the corporations or by hospitals with whom they have contracted to persons subscribing to said plans under contracts which entitle each subscriber to stated hospital care. H. 384 proposes to enact a massage practice act and to establish a board of massage examiners to examine and license persons desiring to practice massage. The bill proposes to define massage as "the use and practice of psychological, Mechanical and Material Health Sciences, to aid in purifying, cleansing and normalizing human tissues, for the preservation of [or] restoration of Health, according to the fundamental principles of anatomy, physiology, and applied Psychology, as may be required. Massage practice employs, among other agencies, Phyto-therapy, Dietetics, Psycho-therapy, Suggesto-therapy, Hydro-therapy, Zone-therapy, Biochemistry, external applications, Electro-therapy, Mechanotherapy, Mechanical and Electrical Appliances, Hygiene, first aid, Sanitation, Heliotherapy, Spinal Manipulation and Manual Bodily Manipulation." S. 211 proposes to require osteopaths to renew their licenses annually with the board of osteopathic examiners and to pay annual renewal fees of $5. As a condition precedent to annual renewal of a license, the holder thereof must present satisfactory evidence of having attended in the previous year the two day educational program as conducted by the Florida osteopathic association.

Illinois

Bills Introduced.—S. 292 proposes to enact a separate osteopathic practice act and to establish an examining committee composed of five osteopaths to examine and license persons desiring to practice osteopathy. The bill proposes to define osteopathy as "a system of practice of the healing arts in all its branches with therapeutics majoring in manipulation." The bill specifically states, however, that a license to practice osteopathy shall not permit the holder thereof to practice major operative surgery but shall entitle the holder to use the necessary minor therapeutic agents in the conduct of his practice. H. 633 proposes a procedure whereby any two or more contiguous counties may be incorporated as a tuberculosis sanatorium district and may establish and maintain a tuberculosis sanatorium with branches, dispensaries and other auxiliary institutions connected with it. S. 371 proposes to grant to a hospital treating a person injured through the negligence of another a lien on all rights of action, claims, judgments or compromises accruing to the injured person by reason of his injury. The bill proposes, however, that the lien may not exceed one fourth of the sum paid or due to the injured person.

Massachusetts

Bill Introduced.—H. 2151 is a report of the Special Commission on Osteopathy, Chiropractic, Food, Drugs and Poisons, in which, among other things, the commission (1) recommends the adoption of a separate chiropractic practice act and the establishment of an independent board of chiropractic examiners to examine and license applicants for licenses to practice chiropractic and (2) submits legislation embodying those recommendations. The commission recommends that chiropractic be defined as "the science of palpating and adjusting the articulations of the human spinal column" and that licensed chiropractors shall not be permitted to practice obstetrics, or to administer or prescribe drugs or to perform surgical operations with the use of instruments.

Michigan

Bills Introduced.—S. 428 proposes that in the management of any hospital supported wholly or in part from taxes no discrimination shall be made against the practitioners of any school of medicine recognized by the laws of the state and that all such legal practitioners shall have equal privileges in treating patients in the hospital. H. 550 proposes a new workmen's compensation act, which will provide compensation for any injury or disease arising out of and in the course of employment of an employer subject to the act. The employer is required to provide for an injured employee such medical, surgical and other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. An injured workman is to be entitled to select his own physician from a list compiled by the Department of Labor on the recommendation of the medical societies of the various counties. S. 460 proposes to enact a law to regulate the manufacture, distribution and advertising of foods, drugs, devices and cosmetics.

New Jersey

Bill Introduced.—S. 205 proposes to enact a separate chiropractic practice act and to establish a board of chiropractic examiners to examine and license persons desiring to practice chiropractic. The bill proposes to define chiropractic as "the science, art and philosophy of things natural; a system of adjusting the vertebral column and of the tissues adjacent thereto by hand for the removal of nerve interference thereby to eliminate the cause of disease." Licentiates are also to have the right to prescribe or regulate the dietary, sanitary and hygienic habits of patients.

New York

Bills Introduced.—S. 1848 and A. 2077 propose to enact a law to regulate the manufacture, distribution, advertising and branding of foods and food products. S. 1892 proposes to prohibit the practice of roentgenology except by licensed physicians, dentists and chiropodists, subject, however, to the conditions and limitations of their respective licenses. The bill proposes to define roentgenology as "that method of medical practice in which examination and demonstration of the normal and abnormal structures and parts of the human body are made by the use of roentgen rays." S. 1893 proposes to authorize the board of supervisors in any county to regulate and license the installation and operation of any machinery, equipment or apparatus to be used for the examination or demonstration of any person or thing by means of fluoroscopic exhibition or shadow imagery registered with photographic materials and the use of roentgen rays. S. 1927 proposes that the medical, dental and nursing care or treatment required for relief clients may be given in whole or in part in cash or by order or in kind, under rules and regulations made by the state board of social welfare.

Oklahoma

Bill Introduced.—H. 638 proposes to require licensed osteopaths to register annually on or before July 1 with the secretary of the state board of osteopathic examiners, to pay annual licensing fees of $2 and to condition the renewal of licenses on the submission of proof that the licentiates have attended at least two days of the annual educational program conducted by the Oklahoma State Osteopathic Association in the year preceding applications for renewal.

Pennsylvania

Bills Introduced.—S. 503 proposes to require all physicians, clinics and hospitals to report to the secretary of health of the commonwealth the name, age, sex and address of a person in whom is found sex abnormality, sex perversion or sex criminal tendencies. H. 1038 proposes to establish a separate chiropody practice act and to establish a board of chiropody examiners to examine and license persons desiring to practice chiropody. The bill proposes to define chiropody as "the diagnosis of foot ailments and the practice of minor surgery upon the feet limited to those structures of the foot superficial to the inner layer of fascia of the foot, the palliative and mechanical treatment of deformities and functional disturbances of the feet and the making of models of the foot and toes or any one or more of such activities." Chiropody is not to include the right to treat communicable or constitutional diseases of the bones, ligaments or muscles of the feet or any other part of the body or to perform any operation on the bones, ligaments, muscles or tendons of the feet involving the use of any cutting instrument or the right to use any anesthetic other than local. H. 1098 proposes to authorize the organization of nonprofit healing arts service corporations to provide to subscribers healing art services, which the bill defines to mean the general and usual services rendered and the care administered by doctors of medicine, doctors of osteopathy, dentists, registered nurses and registered pharmacists.

Texas

Bill Introduced.—H. 489 proposes to enact a new workmen's compensation act requiring employers to pay stated percentages of their payroll into a monopolistic state compensation fund from which will be paid compensation to workmen suffering accidental injury arising out of and in the course of their employment or contracting any one or more of some twenty-six enumerated occupational diseases. Workmen injured or disabled are to be furnished reasonable medical aid, hospital service and medicine and other such treatment as may be necessary to effect a cure from their industrial injuries or disabilities. Apparently, however, workmen are not to be allowed to select physicians of their own choice. However, "if the physician, hospital services, medicines, as furnished by the Board [the administrative agency of the fund] shall not be acceptable to the injured workman, he shall have the right to employ or use such services of his own choice, provided that he submit to proper examination by the physician appointed by the Board, at the expense of the Board."

Wisconsin

Bill Introduced.—A. 692 proposes that the provisions of the medical practice act shall not apply "to a total number of fifty medical physicians who may have been engaged in the actual practice of medicine or surgery in Germany, Austria, Czechoslovakia, or Poland" to whom licenses are issued in the manner set forth in the bill. Briefly, the bill proposes that during the year commencing July 1, 1939, any physician residing in the state who within the last ten years may have been engaged in the continuous practice of medicine in the countries noted may have a license issued to him by the board of medical examiners if he files an affidavit concerning his moral and professional character and the extent and nature of his practice in Europe and also presents an affidavit signed by at least two licensed physicians in the state concerning their knowledge of the applicant. The bill proposes that the number of licenses issued shall not exceed fifty for the year indicated and that no more than five such licenses may be issued in any one calendar month.

WOMAN'S AUXILIARY

Arkansas

Mrs. J. B. Crawford, president, auxiliary to the state medical society, and Dr. George V. Lewis, president, Pulaski County Medical Society, spoke at the February meeting of the auxiliary to the Pulaski County Medical Society. Members of the federated clubs of Little Rock were guests.

At the January meeting of the auxiliary to the Bowie and Miller counties medical societies, Mrs. Kirk Mosley spoke on "Doctors' Wives of the Far East." A collection of Chinese articles was on exhibit.

At the February meeting of the auxiliary to the Sebastian County Medical Society Dr. F. G. Krock spoke on cancer control.

California

Mrs. Charles C. Tomlinson, president, auxiliary to the American Medical Association, spoke before the board of directors of the auxiliary to the California Medical Association in San Francisco February 17.

Dr. Walter H. Brown of Stanford University spoke on "Health Service in Scandinavia" at the January meeting of the auxiliary to the Alameda County Medical Association.

More than 300 doctors and their wives attended the social meeting of the auxiliary at the Athens Athletic Club February 15.

At the January meeting of the auxiliary to the Fresno County Medical Association it was reported that *Hygeia* had been placed in beauty parlors, barber shops, schools, public libraries and clubs. Drs. George W. Walker and A. E. Anderson spoke on "Socialized Medicine." At the February meeting, Mrs. Harold G. Trimble, state Hygeia chairman, spoke on "The Value and Purpose of *Hygeia* to the Public." Dr. Elliot Sorsky spoke on "Comparison of Health Conditions in India with Those in America."

The auxiliary to the Orange County Medical Association has voted to renew twelve subscriptions to *Hygeia* and the *Readers Digest* in Braille for blind persons in Orange County.

The auxiliary to the Riverside County Medical Association was addressed by Dr. Frances Keller Harding on "Medicine Down Under," showing a film of the Fiji Islands.

The auxiliary to the Los Angeles Medical Association met at the Orthopedic Hospital, Los Angeles, January 24. Dr. Robert L. Carroll spoke on "The Therapeutic Theatre," an educational activity provided for hospital patients. The guest speaker was Mme. Gosta Dohlman, wife of Professor Dohlman of Lund University of Sweden.

Illinois

Dr. John R. Neal, Springfield, spoke on "Current Legislative Problems" at a meeting of the auxiliary to the Chicago Medical Society February 1.

Pennsylvania

The auxiliary to the Philadelphia County Medical Society held its annual Christmas Bazaar at the County Medical Society Building December 2 for the benefit of its philanthropies. Dr. Rufus S. Reeves, president-elect of the county medical society, was the speaker at the meeting December 13.

Virginia

The auxiliary to the James City-Williamsburg Medical Society met at the home of the president, Mrs. Frederick R. Persons, January 10, when Dr. E. B. Kilby spoke on socialized medicine.

The auxiliary to the Petersburg Medical Society met at the home of the president, Mrs. Allan Barker, January 23, when Mrs. Wright Clarkson gave a book review on the "Life of Rosalie Slaughter Morton," woman surgeon. A linen shower for the Community Hospital was held February 28. The auxiliary is supporting a memorial bed at the Blue Ridge Sanatorium.

Wisconsin

The auxiliary to the Brown-Kewaunee-Door County Medical Society met December 1 in Green Bay. Mr. J. G. Crownhart, secretary of the State Medical Society of Wisconsin, spoke on "Sickness Care for Wisconsin." There were 125 women in attendance.

Mrs. Robert E. Fitzgerald, president of the auxiliary to the State Medical Society of Wisconsin, spoke at a meeting of the auxiliary to the Sheboygan Medical Society at the home of Mrs. Fred Nause Jr. January 11.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Refresher Course.—The division of maternal and child hygiene of the state department of public health sponsored a refresher course in gynecology and obstetrics in Phoenix April 13-15. Dr. Norman F. Miller, professor of obstetrics and gynecology, University of Michigan Medical School, Ann Arbor, was the instructor.

CALIFORNIA

The Lane Lectures.—Dr. Thomas M. Rivers, director, Hospital of the Rockefeller Institute for Medical Research, New York, will deliver the twenty-seventh course of Lane Lectures of Stanford University School of Medicine, San Francisco, May 22-26. The general title for the lectures will be "Viruses and Virus Diseases."

COLORADO

Portrait of Dr. Edward Jackson.—Dr. Edward Jackson, Denver, observed his eighty-third birthday March 30. As a tribute from friends, a portrait is being painted by Alfred J. Wands, which will be exhibited at a special dedication ceremony but will be hung finally in the Wills Eye Hospital, Philadelphia, where Dr. Jackson received his early training. Born in West Goshen, Pa., Dr. Jackson graduated at the University of Pennsylvania School of Medicine in 1878. He practiced in West Chester and Philadelphia, becoming professor of diseases of the eye at the Philadelphia Polyclinic in 1888. He was surgeon to the Wills Eye Hospital from 1890 to 1894 and from 1896 to 1898. He practiced in Denver from 1894 to 1896 and has practiced there since 1898. He was professor of ophthalmology at the University of Colorado School of Medicine from 1905 to 1921; president of the American Board for Ophthalmic Examinations, 1916-1917; president of the Colorado Commission for the Blind, 1925, and editor of the *American Journal of Ophthalmology* from 1918 to 1928.

ILLINOIS

Pneumonia Control Program.—The state department of public health in cooperation with the U. S. Public Health Service recently launched a program to control pneumonia. Aside from the educational aspects of the plan, efforts are being made to standardize and approve existing laboratories. Antipneumococcus serum for the treatment of type-specific pneumonia has been made available to physicians regardless of the financial status of the patient. Therapeutic antipneumococcus horse serum for types I, II, V, VII, IV and VIII are available in certain areas throughout the state; as the program expands other areas will be added to include the whole state. The only requirements necessary for the physician to obtain serum are: That the bacteriologic diagnostic work for his cases of pneumonia be performed in laboratories which meet the minimum requirements of the state department of public health for typing of pneumonia, and that a treatable type of pneumococcic infection is found; that the duration of the disease has not been longer than ninety-six hours; that the proper report on the use of the serum be filled in, and that all unused vials of serum be returned immediately. The original grant from the federal government was $50,000, of which $38,000 was for serum. When this sum was expended, the state legislature made an emergency appropriation of $75,000 for serum.

Chicago

Society News.—The Chicago Gynecological Society was addressed April 21 by Drs. Paul H. Wosika and Chauncey C. Maher on "The Coexistence of Prolapse of the Uterus, Urologic Pathology and Hypertensive Vascular Disease" and Hilliard E. Miller and Edward Perry Thomas, New Orleans, "Strictures of the Cervix."——A symposium on skull fractures will be presented before the North Shore Branch of the Chicago Medical Society May 9 by Drs. Eric Oldberg, Adrien Verbrugghen and Harold C. Voris.

KANSAS

State Medical Meeting at Topeka.—The eightieth annual session of the Kansas Medical Society will be held at the Masonic Temple May 1-4 under the presidency of Dr. Noble E. Melencamp, Dodge City. The Shawnee County Medical Society is acting as host. Out of state speakers will include:

Dr. Claude D. Head Jr., Washington, D. C., Supportive Measures in the Treatment of Pneumonia.
Dr. John A. Borghoff, Omaha, Contact Dermatoses.
Dr. Waltman Walters, Rochester, Minn., Conservative Surgery of the Kidney.
Dr. James M. Martin, Dallas, Texas, Radiation Therapy in Malignant Diseases.
Dr. Julius Jensen, St. Louis, Treatment of Congestive Heart Failure.
Dr. Arnold S. Jackson, Madison, Wis., The Injection Treatment of Hernia.
Dr. Avery D. Prangen, Rochester, Minn., The Early Diagnosis and Management of the Cross-Eyed Child.
Dr. William S. Horn, Fort Worth, Texas, Chronic Undulant Fever as a Cause of Neurasthenia.
Dr. Jay A. Myers, Minneapolis, Early Diagnosis of Pulmonary Tuberculosis.
Dr. Joseph L. Baer, Chicago, Obstetrical Hemorrhages.
Dr. Mynie G. Peterman, Milwaukee, Epilepsy in Childhood.
Dr. Roy R. Grinker, Chicago, Newer Knowledge of the Central Vegetative Nervous System.
Dr. Louis J. Birsner, St. Louis, The Applied Surgical Anatomy of the Sinuses.

There will be round table luncheons in which the guest speakers will take part. Dr. Melencamp will deliver his presidential address Tuesday afternoon, following the address of welcome by Dr. William C. Menninger, Topeka, president, Shawnee County Medical Society. There will be a stag banquet Monday following the golf and trap shooting tournaments. A luncheon for county society secretaries will be held Wednesday at the Kansas Hotel and all alumni banquets have been planned for Tuesday evening. The annual banquet and dance will be held Wednesday evening when Mr. Robert L. Lund, St. Louis, the guest speaker, will discuss "The Doctor's Stake in Free Enterprise."

KENTUCKY

Lectures on Pediatrics.—A series of lectures on pediatrics will be offered at the Children's Free Hospital, Louisville, beginning April 26 and continuing on Wednesdays until July. The lectures will cover all the principal diseases of children and one hour a day will be given to presentation of interesting cases in the hospital. Dr. Philip F. Barbour is in charge of the course.

Society News.—The Henry County Medical Society was recently reorganized with the following officers: Drs. Walter W. Leslie, New Castle, president; Maurice Bell Jr., Eminence, vice president, and Owen M. Carroll, New Castle, secretary.——Physicians of Carroll, Gallatin and Trimble counties recently organized a tri-county medical society at a meeting in Carrollton with Dr. J. Samuel Brown, Ghent, as president, and Dr. Harold Carl Boylen, Carrollton, as secretary.——Dr. Richard Alexander Bate, Louisville, addressed the Boyd County Medical Association, Ashland, April 4 on "Newer Phases of Practical Endocrinology."

MARYLAND

Dean Lewis Resigns as Professor of Surgery.—Dr. Dean D. Lewis, professor of surgery at Johns Hopkins University School of Medicine, Baltimore, has resigned on account of ill health, it is reported, and will become professor emeritus. Dr. Lewis was born in Kewanee, Ill., in 1874 and graduated at Rush Medical College, Chicago, in 1899. He joined the staff of his alma mater the following year as assistant in anatomy and subsequently served as instructor in surgery, associate professor of surgery and from 1920 to 1924 as professor. He also served in this last capacity at the University of Illinois College of Medicine from January to July 1925, when he went to Johns Hopkins. Dr. Lewis's membership in medical societies includes the American Surgical Association, the American Association of Anatomists, the American Physiological Society, the American Society of Clinical Surgery, the Interurban Surgical Society and the Southern and Western surgical societies. He is an honorary member of the Wisconsin State Medical Society and a member of several foreign surgical societies. During the World War he served as lieutenant colonel and was awarded the Distinguished Service Medal. He is also a member of the Medical Council of the Veterans' Administration. He has been editor-in-chief of the *Archives of Surgery* since its establishment in 1920 and is also editor of a system of surgery. Dr. Lewis has been a member of the House of Delegates of the American Medical

Association, representing the Section on Surgery in 1915, 1916 and 1917. He was also secretary of the Section on Surgery, 1912-1913, and chairman, 1919-1920. In 1933 he was President of the American Medical Association and in 1931 a member of its Council on Medical Education and Hospitals.

MICHIGAN

Symposium on Medical Economics.—The Wayne County Medical Society, Detroit, devoted its meeting at the Detroit Art Institute April 10 to a discussion of medical economics. The speakers were:

Lent D. Upson, Ph.D., The Economic Causes of Social Unrest.
Dr. Henry A. Luce, Comments on the Wagner Bill.
Mr. William J. Burns, Lansing, Voluntary Medical Service Insurance.
Mr. John R. Mannix, Group Hospital Insurance.

Society News.—Dr. Richard M. Davison, Chicago, discussed "Surgical Treatment of Pulmonary Tuberculosis, with Special Reference to a Relatively New Procedure—Extrapleural Pneumothorax" before the Kalamazoo Academy of Medicine March 21.——Dr. Lawrence Reynolds, Detroit, discussed "Cystic Disease of the Lungs" before the Jackson County Medical Society March 21.——Dr. Harold M. Teel, Brookline, Mass., addressed the Calhoun County Medical Society, Battle Creek, March 7 on "Use and Abuse of Pituitrin in the Conduction of Labor."

MINNESOTA

The Bell Lecture on Tuberculosis.—Dr. Henry C. Sweany, Chicago, presented the John W. Bell Lecture on tuberculosis before the Hennepin County Medical Society April 3; his subject was "The Tuberculosis Problem Viewed in the Light of Recent Pathologic Studies." The lecture is sponsored by the Hennepin County Tuberculosis Association.

MISSOURI

The Terry Lecture.—Dr. Lewis Hill Weed, professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, will give the first lecture under the Robert J. Terry Lectureship Foundation, Wednesday, May 17, at 4:30 p. m., in the auditorium of the Washington University School of Medicine, Scott and Euclid avenues, St. Louis. His subject will be "Anatomy in the Medical Curriculum." The lecture is open to the public without charge.

NEBRASKA

Society News.—Dr. Peter T. Bohan, Kansas City, Mo., addressed the Omaha-Douglas County Medical Society, Omaha, March 14 on coronary disease.——Drs. Paul M. Bancroft and Archibald R. McIntyre, Omaha, addressed the Lancaster County Medical Society, Lincoln, recently on "Relationship of the Pineal Gland to Sexual Precocity" and "Experimental Work with Vitamins" respectively.

NEW YORK

Society News.—Dr. Perrin H. Long, Baltimore, addressed the Medical Society of the County of Westchester, White Plains, April 18, on "Clinical Use of Sulfanilamide, Sulfapyridine and Allied Compounds."——Dr. John C. McClintock, Albany, addressed the Dutchess County Medical Society, Poughkeepsie, April 12 on "Some Thyroid Problems."——Drs. Paul V. Newland and Adrian S. Taylor, Clifton Springs, addressed the Ontario County Medical Society, Clifton Springs, April 11 on "Diabetic Coma" and "Common Diseases and Injuries of the Hip" respectively.——Dr. William H. Hobbs, Binghamton, addressed the Broome County Medical Society, Binghamton, April 11 on transurethral resection in the treatment of vesical neck interference.——Dr. Louis C. Kress, Buffalo, addressed the Onondaga County Medical Society, Syracuse, April 4 on "The Part of the General Practitioner in the Control of Cancer" and the proposed state plan for cancer control.——Robert Sealock, Ph.D., Rochester, addressed the Jefferson County Medical Society March 9 on "Vitamins from a Functional Viewpoint."

New York City

Society News.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address the Medical Society of the County of Kings, Brooklyn, May 23 on "Current Aspects of Medical Legislation."

Plans for the Twelfth Graduate Fortnight.—The New York Academy of Medicine announces that its twelfth Graduate Fortnight will be held from October 23 to November 3. The subject this year will be "The Endocrine Glands and Their Disorders." A complete program and registration blank may be secured by addressing Dr. Mahlon Ashford, The New York Academy of Medicine, 2 East One Hundred and Third Street, New York.

Obstetrics and Infantile Paralysis.—Drs. Samuel Kleinberg and Morris T. Horwitz are conducting at the Hospital for Joint Diseases an investigation of the obstetric difficulties in patients who have had infantile paralysis. The study is being conducted under a grant from the National Foundation for Infantile Paralysis. Physicians who may know of any such cases are asked to communicate with Dr. Kleinberg or Dr. Horwitz, care of the Research Department, Hospital for Joint Diseases, One Hundred Twenty-Third Street and Madison Avenue, New York.

Convalescent Measles Serum Available.—The New York Department of Health directs attention to its service for providing convalescent measles serum to hospitals and physicians. The serum is prepared in the Manhattan Convalescent Serum Laboratory in the health department's William Hallock Park Laboratory from blood obtained from persons recovered from measles. It is proved sterile and Wassermann negative before it is released, its distribution has been licensed and is under the supervision of the U. S. Public Health Service. Because the laboratory is a nonprofit organization, the serum is furnished to hospitals and physicians at cost of production. Further information may be obtained from Dr. William Thalhimer, director of the laboratory, Fifteenth Street and East River.

Health Precautions at World's Fair.—To safeguard the health of visitors at the New York World's Fair, the municipal department of health has established a branch of its activities on the exposition grounds to enforce the special rules of sanitation that have already been set up. A staff of twenty-four physicians, assisted by thirty nurses, will be in attendance at all times. There are seven first aid stations, each to provide a waiting room, surgery, nurses' and physicians' rooms, and wards for men and women. Serious cases will be temporarily hospitalized and transfer made later to outside hospitals by ambulance. The Fair Corporation operates five air-conditioned ambulances and a truck with portable x-ray equipment. The truck is also fitted up as a developing room, making possible immediate roentgenographic diagnosis. A section of pneumatology has been established at the fair, covering a wide range program in this field of the prevention of asphyxial death. Steps have been taken to enforce all regulations pertaining to the examination of food handlers and food establishments and to the disposal of garbage. Under the terms of these regulations, all glasses, cutlery and crockery used in food purveyance anywhere in the fair are required to be properly washed in a solution of soap, soda or other suitable cleansing powder and treated before each use with a final rinse of hot water at 175 F. for a period of one minute, the temperature to be registered by a thermometer. These installations must be equipped with a locking and timing device to guarantee the time required. Food handlers will be examined once a month and a card issued which must be produced on request by health inspectors. Every effort has been made to eliminate all breeding places of mosquitoes and other insects on the fair site.

NORTH CAROLINA

Society News.—Speakers at a meeting of the Catawba Valley Medical Society, Lenoir, March 14, were Drs. Frederick M. Dula, Lenoir, on "Intestinal Obstruction"; Yates S. Palmer, Valdese, "Diagnosis and Treatment of Anal Fissure" and Alfred A. Kent Jr., Granite Falls, "Epidemic of Acute Benign Lymphocytic Meningitis."——Dr. William B. Porter, Richmond, Va., addressed the Wake County Medical Society, Raleigh, March 9 on "Nutritional Deficiencies and Their Relation to the Clinical Course of Heart Disease."——Dr. Maurice Barnes Woodhall, Durham, addressed the Guilford County Medical Society, Greensboro, April 7 on "Intervertebral Disk Displacement: A Common and Remediable Cause for Sciatica and Back Pain."——Dr. Irving Graef, New York, addressed the Buncombe County Medical Society, Asheville, April 3 on "Advances in the Pathology of Renal Disease."

NORTH DAKOTA

State Medical Meeting at Fargo.—The annual meeting of the North Dakota State Medical Association will be held in Fargo at the city auditorium May 8-10. The guest speakers listed on a tentative program include:

Dr. Elmer M. Jones, St. Paul, Diagnosis and Management of the Surgical Gallbladder.
Dr. Henry E. Michelson, Minneapolis, Problems of Latent and Wassermann-Fast Syphilis; Dermatology for the General Practitioner.

Dr. Louis A. Buie, Rochester, Minn., Office and Hospital Management of Ano-Rectal Diseases.
Dr. Frank J. Hirschboeck, Duluth, Minn., Cardiac Emergencies; Diagnosis and Treatment of Gastrointestinal Hemorrhage.
Dr. Solon Marx White, Minneapolis, Hypertension.
Dr. Frederick C. Rodda, Minneapolis, An Approach to Some Common Behavior Problems.

Among the North Dakota physicians who will present papers are:

Dr. Leonard W. Larson, Bismarck, Medical Legislation.
Dr. Archibald D. McCannel, Minot, Diagnosis and Treatment of Eye, Ear, Nose and Throat Conditions Which Are of Particular Interest to the General Practitioner.
Dr. Harry J. Fortin, Fargo, Emergency Orthopedic Problems.
Dr. George A. Dodds, San Haven, Indication and Technic of Artificial Pneumothorax, Thoracoplasty and Extrapleural Pneumothorax in the Treatment of Pulmonary Tuberculosis.

OHIO

Another Society of Anesthetists.—The Ohio Society of Anesthetists will hold its organization meeting at the Hotel Waldorf, Toledo, May 4, in joint session with the American Society of Anesthetists. The meeting will open with clinics by the Toledo Society of Anesthetists, following which a constitution will be adopted by the state society and the election and installation of officers will take place. The speakers will include:

Dr. Maurice P. Cooper, Toledo, The Anesthetic Fire and Explosion Hazard.
Dr. Frederic Schreiber, Detroit, Cerebral Anoxia and Anesthesia.
Dr. John S. Lundy, Rochester, Minn., Intravenous Anesthesia.
Dr. Brant B. Sankey, East Cleveland, Combined Inhalation and Spinal Anesthesia.
Dr. Hubert R. Hathaway and M. Digby, Madison, Wis., A Free Air-Way Below the Larynx.

A business session of the American Society of Anesthetists will be held in the evening.

PENNSYLVANIA

Society News.—Dr. Richard A. Kern, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, April 11 on clinical allergy.——Dr. Ralph M. Tyson, Philadelphia, was the speaker at a meeting of the Washington County Medical Society, Washington, April 12 on "Care of the Newborn Child."——At a meeting of the Cambria County Medical Society, Johnstown, April 13 Dr. Stanley P. Reimann, Philadelphia, gave an address on cancer.——Dr. Joseph H. Barach, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, April 6, on "Simplified Treatment of Diabetes."

Philadelphia

University News.—Dr. Arthur D. Kurtz, who died January 21, left a bequest of $4,000 to Temple University to endow a scholarship in memory of his son, who died while a student at Temple University High School.

Personal.—Dr. Leopold S. Vaccaro has resigned as medical director of the state workmen's insurance fund, department of labor and industry, to return to private practice.——Friends and co-workers of Dr. John Claxton Gittings gave a dinner in honor of his sixty-fifth birthday March 13 at the Barclay Hotel. Dr. Albert Graeme Mitchell, Cincinnati, was toastmaster and presented to the University of Pennsylvania a portrait of Dr. Gittings, contributed by his friends. Dr. Gittings is William H. Bennett professor of pediatrics at the university, from which he graduated in 1895.——Dr. George W. Miller, Norristown, has been appointed professor of general anatomy in the Temple University School of Dentistry to succeed the late Dr. Addinell Hewson. Dr. Miller was formerly associate in anatomy at Jefferson Medical College and was at one time on the staff of the department of applied anatomy at Temple University School of Medicine.——At the recent Founder's day of Temple University, when awards were presented to alumni for conspicuous service, Dr. James Marsh Alesbury received the medical award.

SOUTH CAROLINA

Colonel Moncrief Appointed Superintendent of Sanatorium.—Col. William H. Moncrief, director of the Army and Navy General Hospital, Hot Springs National Park, Ark., has been appointed superintendent of the South Carolina Tuberculosis Sanatorium, State Park, to succeed Dr. Ernest Cooper, who is retiring after many years' service. Colonel Moncrief will assume the position about May 1, when he is eligible for retirement from the army, according to a newspaper account. A graduate of Southern Medical College, Atlanta, in 1897, Colonel Moncrief served in the Spanish-American War and after a period of private practice in Atlanta entered the army in 1902. He served overseas in the World War and since 1920 has commanded Fitzsimons, Sternberg, William Beaumont and Walter Reed general hospitals of the army previous to his service at the general hospital in Hot Springs National Park. Dr. Cooper was made the first superintendent of the sanatorium in 1915, when it had sixteen beds in an open pavilion. It now has a capacity of 500 patients. Dr. Cooper was born in North Carolina and graduated from Johns Hopkins University School of Medicine, Baltimore, in 1910.

TEXAS

State Medical Meeting at San Antonio.—The seventy-third annual session of the State Medical Association of Texas will be held at the Gunter Hotel, San Antonio, May 9-11, under the presidency of Dr. Ernst W. Bertner, Houston. Out of state speakers will include:

Dr. Irvin Abell, Louisville, President of the American Medical Association, Medicine in the Changing Social Order.
Dr. John Zahorsky, St. Louis, Psychology in Pediatrics.
Dr. Hubley R. Owen, Philadelphia, What Are the Duties and Responsibilities of the General Practitioner in the Treatment of Fractures? Unrecognized Fractures.
Dr. Eugene P. Pendergrass, Philadelphia, Irradiation Therapy of Infections.
Dr. Wiley R. Buffington, New Orleans, Medical Ophthalmology and the General Practitioner.
Dr. James N. Baker, Montgomery, Ala., A Plea for Greater Unity Between the Medical and Public Health Professions.
Dr. Charles F. Craig, San Antonio, Modern Treatment of Malaria Infections.
Dr. Chester S. Keefer, Boston, Diagnosis of the Causes of Obscure Fever.
Dr. Russell L. Haden, Cleveland, Use of Iron and Liver in the Treatment of Anemia.
Dr. Hugh H. Young, Baltimore, The Prostate: Medical and Surgical Aspects.
Dr. Henricus J. Stander, New York, General Considerations of the Toxemias of Pregnancy.

With the Bexar County Medical Society as host, an elaborate program of entertainment has been planned including golf, skeet and trap shoot, alumni banquets and luncheons. Other societies meeting during this time include the Texas Railway and Traumatic Surgical Association, Texas Neurological Society, Texas Association of Medical Anesthetists, Texas Society of Gastro-Enterologists and Proctologists and Texas Dermatological Society. The woman's auxiliary to the State Medical Association of Texas will hold its twenty-first annual session.

WASHINGTON

New Committees of State Society.—The board of trustees of the Washington State Medical Association at a meeting in January created two new committees, one on public relations and one on postgraduate medical education. Dr. Clark C. Goss, Seattle, is chairman of the committee on public relations and the members are Drs. Henry S. Atwood, Yakima; Jo B. Blair, Vancouver; John C. Lyman, Walla Walla; Sydney M. MacLean, Tacoma; Edwin A. Nixon, Seattle, and Otto M. Rott, Spokane. Dr. Homer D. Dudley, Seattle, is chairman of the committee on postgraduate medical education and members are Drs. Donald G. Evans, Richard J. O'Shea and Charles E. Watts, all of Seattle.

GENERAL

Meeting of Chest Physicians.—The American College of Chest Physicians will hold its annual meeting at the Chase Hotel, St. Louis, May 13-14, under the presidency of Dr. Champneys H. Holmes, Atlanta, Ga.

Nu Sigma Nu Luncheon.—The annual Nu Sigma Nu Fraternity alumni luncheon will be held at the Statler Hotel in St. Louis, Wednesday, May 17, during the period of the annual session of the American Medical Association. Additional information may be had from Dr. Drew Luten, 3720 Washington Boulevard, St. Louis.

Dr. Spies Awarded Phillips Medal.—Dr. Tom D. Spies, associate professor of medicine, University of Cincinnati College of Medicine, Cincinnati, was awarded the John Phillips Memorial Medal by the American College of Physicians at its annual meeting in New Orleans March 29. Dr. Spies was given the medal for "outstanding contributions to the science of nutrition and particularly for his studies on the nature and character of pellagra." Dr. Spies graduated at Harvard Medical School in 1928.

Advisory Committee to the Red Cross.—Dr. Livingston Farrand, Brewster, N. Y., has been made chairman of a medical advisory committee to the American Red Cross, it was announced March 15. Other members of the committee are

Drs Thomas Parran, surgeon general, U S Public Health Service, Washington, D C, Waller S Leathers, dean, Vanderbilt University School of Medicine, Nashville, Tenn, David P Barr, professor of medicine, Washington University School of Medicine, St Louis, Martha M Eliot, assistant chief of the Children's Bureau, Washington, D C, Ross T McIntire, surgeon general, U S Navy, Charles R Reynolds, surgeon general, U S Army, and Edwards A Park, pediatrician of Johns Hopkins Hospital, Baltimore

Research in Ophthalmology.—The Association for Research in Ophthalmology, Inc, will hold its tenth annual meeting in St Louis May 16 The following program will be presented

Dr Theodore E Sanders, St Louis, Experimental Ocular Hypersensitivity
Drs Theodore L Terry, Boston, Julian F Chisholm Jr, Savannah, Ga, and Albert L Schonberg Cleveland Studies on Surface Epithelium Invasion of the Anterior Segment of the Eye
Dr Maynard A Wood, Iowa City, A Study of Methemoglobin-Producing Organisms in Ocular Inflammations
George K Smelser, Ph D, New York Relation of Muller's Orbital Muscle to the Pathology of Retrobulbar Tissues Obtained in Experimentally Produced Exophthalmos
Dr Earl L Burky, Robert Redvers Thompson, Ph D, and Helen D Zepp, A B, Baltimore, Ocular Reactions of Horses and Rabbits Infected with Strains of Brucella Recovered from Horses with Periodic Ophthalmia
Dr James H Allen Iowa City Staphylococcus Conjunctivitis—Experimental Reproduction with Staphylococci
Louis Jubanelle Ph D, St Louis, An Immunological Study of Trachoma
Dr Arthur A Knapp, New York Vitamin D Complex in Myopia, Etiology, Pathology and Treatment

Dr. Stevenson Succeeds Dr. Hincks.—Dr George S Stevenson, New York, director of the division of community clinics of the National Committee for Mental Hygiene, has been appointed medical director to succeed Dr Clarence M Hincks Dr Hincks has been dividing his time since 1931 between the national committee and the National Committee on Mental Hygiene of Canada and now returns to the latter organization Dr Stevenson graduated from Johns Hopkins University School of Medicine, Baltimore, in 1919 After graduation he taught psychiatry at Cornell University Medical College, New York, and the University of Minnesota Medical School, Minneapolis, until he joined the National Committee for Mental Hygiene in 1926 as field consultant for the division on community clinics He became director of the division in 1927 He is active in various organizations for mental hygiene and has been secretary and president of the American Orthopsychiatric Association

Medical Women's Association Meeting.—The twenty-fourth annual convention of the American Medical Women's Association will be held at the Hotel Jefferson, St Louis, May 12-14 A banquet honoring past presidents of the association will open the session, at which Drs Harriet S Cory and Helen L B Gage, St Louis, will speak on "What Next for Social Hygiene?" and "The Influence of the Autonomic System upon Certain Diseases of the Upper Respiratory Tract," respectively Other speakers on the program will include

Dr Aphrodite M J Hofsommer, Webster Groves, Mo, Hard of Hearing in the Public Schools
Dr Lois C Wyatt, Kirkwood, Mo, Meningitis Complicating a Case of Chickenpox
Dr Ellen S Loeffel Webster Groves Mo Recent Developments in the Endocrine Therapy of Menstrual Disorders
Dr Mary Alice Townsend DeMotte Phillipsburg, Kan, Status of Medical Practice in Western Kansas
Dr Lillian R Smith, Lansing, Mich, Maternity and Child Welfare

At the inaugural banquet Saturday evening Dr Margaret G Smith, St Louis, will discuss "The St Louis Encephalitis" and Dr Nelle S Noble, Des Moines, will present the inaugural address on "Women in Medicine"

The Twenty-Fifth Annual Golf Tournament.—Fifty trophies and prizes will be awarded in the nine events of the twenty-fifth annual tournament of the American Medical Golfing Association at the banquet at Norwood Hills Country Club, St Louis, May 15 To reach the country club drive out Florissant Road to Lucas and Hunt Road, then north to the country club This is a thirty-six hole competition, beginning at 7 30 a m and 2 30 p m Only active fellows of the American Medical Golfing Association may compete for prizes Members should bring their membership cards to the tournament to facilitate registration The dinner, the green fees for both courses, tournament fee, refreshments, entertainment and prizes are all covered by the $6 fee New fellows of the golfing association pay an additional enrollment fee of $3 All members of the golfing association are cordially invited to attend this silver anniversary of the American Medical Golfing Association Additional information will be provided by Bill Burns, executive secretary, 2020 Olds Tower, Lansing, Mich

Association of the History of Medicine.—The fifteenth annual meeting of the American Association of the History of Medicine will be held at the Hotel Chalfonte, Atlantic City, N J, April 30-May 1, under the presidency of Dr Walter R Steiner, Hartford The speakers will include.

Morris C Leikind, Washington, D C, An Episode in the History of Smallpox Vaccination in New Hampshire
Walton B McDaniel, Ph D Philadelphia, The Place of the Amateur in the Writing of Medical History
Dr Howard Dittrick Cleveland Nursing Cans
Dr Franklin H Church, Salem, N J, Syphilis of the Center of the Face
John W Draper, Ph D, Morgantown, W Va, The Old Age of King Lear
Dr Savas T Nittis, Detroit, The Hippocratic Oath in Reference to Lithotomy A New Interpretation, with Historical Notes on Castration
Dr Iago Galdston New York, Ideological Basis of Discoveries
Dr David Riesman, Philadelphia Clinical Teaching in America with Some Remarks on Early Medical Schools
Dr Jabez H Elliott, Toronto John Gilchrist, 1792 1859, A New England Physician in Upper Canada
Dr George Rosen, Brooklyn, Occupational Diseases of English Seamen During the Seventeenth and Eighteenth Centuries
Albert Deutsch, New York, Provision for the Sick Poor in Colonial Times
Dr Robert S Drews, Detroit, The History of the Care of the Sick Poor in Detroit

Dr Steiner will deliver his presidential address Monday evening on "Some of Louis' Distinguished American Pupils" and Dr William G Leaman Jr, Philadelphia, will discuss "Medical History in Clinical Teaching"

Society for Investigative Dermatology.—The second annual meeting of the Society for Investigative Dermatology will be held at the De Soto Hotel, St Louis, May 16 Dr Joseph V. Klauder, Philadelphia, will deliver the presidential address, on "Clinical and Experimental Study of Interstitial Keratitis" Other speakers will include

Dr Cornelius P Rhoads, New York, The Physiological Disturbance Associated with Premalignant Changes of the Oral Cavity
Irvin H Blank, Ph D, Boston, *pH* Measurements on the Surface of Normal Skin
Dr Matthew Walzer, Brooklyn, Contact Reaction in Atopic Children
Dr Horton C Hinshaw and W H Feldman, D V M, Rochester, Minn, A Histopathologic Study of the Intracutaneous Tuberculin Reaction in the Human Being
Dr Carl W Laymon, Minneapolis, Histamine in the Treatment of Urticaria and Atopic Dermatitis
Dr Joseph Harkavy, New York Tobacco Skin Reactions and Their Clinical Significance
Dr Leon Goldman, Cincinnati, Effect of Fever Artificially Induced on the Skin Sensitivity of Guinea Pigs to Turpentine
Dr Stephen Rothman, Julius M Coon Ph D, and Mrs Harriet Stenn, Chicago, Studies on Acetylcholine in Patients with Skin Diseases
Drs George P Vryonis and Hugh J Morgan, Nashville, The Number of Treponema Pallidum in the Superficial Lesions of Human Syphilis
Dr Joseph M Thuringer, Oklahoma City, Mitotic Index of Palmar and Plantar Epidermis in Response to Stimulation
Drs Charles W Barnett and George V Kulchar, San Francisco, Experimental Studies on the Salivary Transmission of Syphilis
Dr P. Arthur Delaney, Chicago, Modern Technical Methods in Cutaneous Histopathology
Zola K Cooper, Ph D St Louis Mitotic Rhythm in Human Epidermis
Dr Lester W Kimberly, Iowa City, Blood Plasma Bromide Levels in Bromoderma
Dr Camille Kereszturi, New York, Primary Tuberculosis of the Skin

Eye, Ear, Nose and Throat Session.—The forty-fifth annual meeting of the American Laryngological, Rhinological and Otological Society will be held at the Drake Hotel, Chicago, May 9-11, under the presidency of Dr Harold I Lillie, Rochester, Minn A symposium on care of the patient following operations for sepsis of otitic origin will open the scientific session with Drs William E Grove, Milwaukee, Jacob Marion Sutherland, Detroit, and Thomas C Galloway, Evanston, Ill, as the speakers One session will be devoted to the care of mastoid wounds

Dr Marvin F Jones New York, Following the Complete Mastoid Operation Sinus Thrombosis and Operations on the Petrous Pyramid
Dr James Morrisset Smith, New York Following the Radical Mastoid Operation of the Modified and Standard Types
Dr Harold G Tobey, Boston, Following Operations on Abscess of the Brain

Speakers in a symposium on final results in operations for chronic suppurative paranasal sinusitis will include

Dr Bert E Hempstead, Rochester, Minn, End Results in Intranasal Operations for Maxillary Sinusitis
Dr Ebenezer Ross Faulkner New York, End Results of Intranasal Operations on the Ethmoid Frontal and Sphenoid Sinuses
Dr Samuel Salinger, Chicago End Results in External Operations on the Maxillary Sinus
Dr Millard F Arbuckle St Louis End Results in External Operations on the Frontal Ethmoid and Sphenoid Sinuses

A symposium on voice defects will include the following

Dr James S Greene New York, Vocal and Verbal Syndromes Their Rhinolaryngologic Significance
Dr Irving Wilson Voorhees, New York Voice Defects as Related to Hearing Defects
Dr Chevalier L Jackson, Philadelphia, The Voice After Direct Laryngoscopic Operations, Laryngofissure and Laryngectomy

Dr Lyman G Richards, Boston, will also address the meeting on 'Cuts and Captions' Five Editorial Years in Retrospect"

A Complete War Time Plan of Hospital Organization

In the great war the principal hospitals of the country were extensively used for the treatment of wounded soldiers. If another European war occurs they will be put to a quite different use. The bombing from the air of crowded cities has made the position of these hospitals dangerous. They will be used as casualty clearing stations for the immediate treatment of numerous civilian casualties which are expected, and the seriously wounded who cannot be discharged will be removed to base hospitals in safer localities. Plans for this purpose have now been worked out in the greatest detail. Thus London has been divided into ten sectors. These contain the great teaching and large municipal hospitals which have the personnel and equipment for dealing with casualties on a large scale. Other hospitals and institutions have adequate accommodation and can be cleared of their normal patients and upgraded to the status of casualty hospitals in time of emergency. From these the injured would be transferred as soon as possible to affiliated casualty base hospitals in outer areas.

FIRST AID POSTS AND MOBILE UNITS

First aid posts are to be established wherever possible and supplemented by mobile units consisting of vehicles carrying equipment and medical personnel. Each unit is to consist of an automobile 8 feet 6 inches long, 5 feet wide and 6 feet high, fitted with cupboards packed with medical and surgical material. A physician and a nurse will travel in this and auxiliary personnel will follow in a car. One physician at least is to attend at every first aid post. An annual fee is to be paid in peace time to physicians in charge of first aid posts in consideration of their supervising the collective training of the auxiliary personnel assigned to the post. In London the land ambulance service will be supplemented by a river service on the Thames from its estuary up to Teddington.

Surgery in Diabetes

In a discussion at the Royal Society of Medicine Dr. H. P. Himsworth said that surgery in diabetes depended on whether the patient could be sent to the operating room with his diabetes balanced. If not, the surgical technic might have to be modified. Knowledge of the blood sugar level was of little value, for it was not correlated with the clinical state. All the necessary information could be obtained from a series of specimens of the urine. The most important chemical sign was ketonuria, for it showed that the diabetes was grossly out of control and the patient not fit for operation. When time was available the preparation of the patient with uncontrolled diabetes differed from the routine balancing in only one respect: he must receive an adequate amount of food from the onset—at least 1,800 calories and from 180 to 200 Gm. of carbohydrate. The dose of insulin should be raised until ketonuria was completely abolished and glycosuria reduced to a minimum. Protamine zinc insulin should not be used unless a long time was available for observation.

For minor operations under local anesthesia with evipal or with tribromethanol in amylene hydrate no special measures were necessary, but a major operation under a volatile anesthetic required special preparation. The meal and insulin next before the operation should be omitted, but two or three hours before 50 Gm. of sugar in lemonade should be given and, as the patient was put on the trolley, 35 units of insulin subcutaneously. If he was on protamine zinc insulin and the operation was fixed for the morning, the same preparation should be given without breakfast or protamine zinc insulin. If the operation was in the afternoon he should receive the usual dose of protamine zinc insulin and luncheon should be omitted, but three hours before operation 30 Gm. of sugar should be given and 10 units of insulin as he went to the operating room. Ether produced vomiting, which by interfering with the intake of food might complicate treatment, and chloroform was condemned by authorities. Postoperative dehydration must be avoided and diabetic ketosis averted, the former by administration of dextrose saline solution and water, the latter by administration of insulin. After the operation a patient who could take food by mouth was given sweet lemonade. Every specimen of urine was tested, if there were no ketones, by Benedict's solution; if the precipitate was red the patient should have 20 units of insulin; if yellow, 50; if green, 10. But if there was no precipitate, no insulin. If ketonuria was present, more carbohydrate should be given and 25 units of insulin for each 50 Gm. of sugar. If the patient could not take sugar by mouth during the first twelve hours he should have insulin according to the color schedule. Ketosis should be combated by intravenous dextrose and saline solution, one pint an hour for two or three hours, and, for every 50 Gm., of dextrose, from 30 to 50 units of insulin should be given according to the severity of the ketosis. If after twelve hours dextrose could still not be given by mouth, more dextrose and saline solution should be injected intravenously with 25 units of insulin.

The state of ketonuria determined whether an emergency operation could be undertaken at once. It was usually possible to wait six hours. If much ketosis was still present, 10 per cent dextrose solution could be infused during the operation and afterward until the ketosis disappeared. If during preparation severe glycosuria developed and ketonuria appeared, sepsis was probably present and operation must not be delayed.

James Risien Russell

The death at the age of 75 of James Risien Russell has removed a great neurologist and great teacher. He graduated at Edinburgh in 1886 and took the gold medal at his M.D. examination. He came to London for postgraduate study at St. Thomas's Hospital and after further study at Berlin and Paris became resident medical officer at the National Hospital, Queen Square, the home of British Neurology, then at its zenith. On its staff was a galaxy consisting of Hughlings Jackson, Ferrier, Gowers, Horsley, Beevor and Bastian. Russell was in turn appointed registrar, pathologist, assistant physician and physician. By a succession of original papers published from 1890 to 1900 and his skill as a clinician and teacher, he achieved a standing beside these great British neurologists. These papers included experimental studies on the functions of the cerebellum, its afferent and efferent pathways, the constitution of the brachial and lumbosacral plexuses and the effects of various lesions of the central nervous system on the knee jerk. With James Taylor he made a critical study of the suspension treatment of tabes dorsalis. In 1900 he published with Batten and Collier a classic paper on the disease they termed "subacute combined degeneration of the spinal cord." He pointed out that cerebellar ataxia is a feature of voluntary as opposed to reflex movements. His command of language and clinical acumen attracted crowds to his clinics. It was said of him by the students that he knew all that the other neurologists knew and had something of his own in addition. He was a president of the Neurological Section of the Royal Society of Medicine, corresponding member of the Société de neurologie of Paris and honorary member of the Canadian Medical Association. He contributed many papers to the medical journals and neurologic chapters to Allbutt's System of Medicine, the Encyclopaedia Medica, Quain's Dictionary of Medicine and Gibson's Textbook of Medicine.

Clinical Versus Biologic Cure of the Avitaminoses

At the February 28 meeting of the Académie de médecine of Paris, Drs. Georges Mouriquand and Jacques Rollet called attention to the necessity of making a distinction between relief of symptoms due to an A or C avitaminosis and cure of the underlying tissue changes which result from such avitaminoses. By the latter is meant the loss of sensibilization to a recurrence of the particular avitaminosis. Guinea pigs which have been subjected to a C avitaminosis diet present typical scorbutic lesions as early as the fifteenth day, which increase in severity from that period onward. If the animals are given a strong dose of ascorbic acid toward the twentieth day, all the clinical evidences of the avitaminosis recede rapidly in a few days. From ten to thirty days after apparent cure, no typical scorbutic lesions can be found at necropsy. If the surviving apparently cured animals are again placed on a C avitaminosis diet and other guinea pigs, to be used as controls, are given the same diet, the apparently cured animals show scorbutic lesions between the third and sixth days, whereas the controls present only the typical lesions from the fifteenth day onward. Only after a long period of treatment with ascorbic acid do the animals which show early evidence of recurrence appear to be cured again. This period varies from sixty to eighty days. This persistence of the lesions of C avitaminosis and sensitization in the animals subjected to a second C avitaminosis diet after apparent cure coincides with the persistence of a certain fibrillary condition of the medulla of the bones, and this disappears only when complete neutralization is obtained. Similar results were obtained in rats subjected to A avitaminosis. After use of an A avitaminosis diet, there appears a typical xerophthalmia, which recedes rapidly after carotene is given. If, however, the A avitaminosis diet is given again, the xerophthalmia reappears in ten or fifteen days, whereas in the control animals, which have been given the A avitaminosis diet for the first time, the xerophthalmia appears at about the thirtieth day.

These experimental observations indicate that the apparent clinical cure of patients suffering from A or C avitaminosis is not a real cure. Complete cure depends on the disappearance of sensibility on the part of the tissues. This necessitates a prolonged cure in order to prevent recurrence of symptoms and bring about a state of biologic "neutrality."

Serotherapy of Appendicitis and Perforative Peritonitis

Prof. M. Weinberg of the Pasteur Institute read a paper at the Nov. 29, 1938, meeting of the Académie de médecine in which he warmly recommended the use of an antigangrene and anticolibacillus serum in all cases of acute appendicitis, especially if complicated by peritonitis. This treatment has encountered strong opposition on the part of some of the leading surgeons in Paris because it might encourage the practitioner to await the outcome of the injection of the serum and consequently result in an increased mortality as compared with that of immediate operation in all cases of acute appendicitis. At the February 21, 1939, meeting of the same society, Professor Weinberg answered the criticisms of those who were opposed to such preoperative serotherapy. He stated that he wished to be understood as being in favor of operation in all cases at some period. For patients who were far away from hospitals, for example on islands, in the colonies or on ships at sea, serotherapy was distinctly indicated. In addition, many surgeons preferred to postpone operation, if possible, until an acute attack had subsided. Their patients would be distinctly benefited by preoperative serotherapy directed toward combating the bacteria most commonly found in appendicitis and appendicular peritonitis. In ten cases studied bacteriologically, the defensive powers of the patient were distinctly increased as a result of serotherapy. Even in cases of immediate operation, serotherapy is indicated in the interval preceding the operation.

In the discussion, Prof. H. Vincent stated that Bacillus perfringens was rarely found in cases of appendicitis and even when present did not appear to have any marked pathogenic properties as compared with Bacillus coli. If certain surgeons, as Dr. Weinberg claimed, had observed a lower mortality rate following the use of a polyvalent antigangrene and an anticolibacillus serum, the reason for this improvement was not the action of these specific serums. It must be remembered that ordinary horse serum contains a variable quantity of antibodies which act on a large number of bacteria, especially B. perfringens, B. coli and Streptococcus faecalis (enterococcus). But Dr. Vincent supported the contention of Dr. Weinberg that serums which had a specific action on these three groups of bacteria should be used because there were cases in which horse serum alone did not contain sufficient antibodies to combat the toxins of B. perfringens, B. coli and Streptococcus faecalis.

Fiftieth Anniversary of Pasteur Institute of Paris

The Academy of Science started a subscription in 1888 to erect suitable buildings to house the work of Pasteur and his associates. The Pasteur Institute was opened Nov. 14, 1888, and plans had been made to celebrate its fiftieth anniversary last fall. Owing, however, to the disturbed condition of international affairs, the celebration was postponed to March 15 of this year. In the presence of President Lebrun and of Minister of Public Health Rucart, papers were read by Prof. Louis Martin, director of the Pasteur Institute, by Prof. Gaston Ramon of the branch institute at Garches in one of the Paris suburbs, and by the grandson of Louis Pasteur, Prof. Pasteur Vallery-Radot.

Following the reading of these three papers, a gold medal was awarded Dr. Harry Plotz of New York, at present head of one of the laboratories of the Pasteur Institute, for his research work on the virus of various infectious diseases. A gold medal was also awarded Dr. A. Saenz, now of Uruguay, for his work on the bacteriology of tuberculosis. Prof. Louis Martin in his paper reviewed the life of Pasteur, in calling attention to the opposition which he encountered to his pioneer work in bacteriology. The first course in March 1889 was given at the institute by one of Pasteur's assistants, Professor Roux, whose research on diphtheria made his name almost as well known in the scientific world as that of Pasteur. During recent years the activities of the institute have been especially directed toward the study of the viruses of diseases affecting both animals and man.

Professor Ramon first reviewed the work of Roux and Yersin, who discovered the toxin of diphtheria in 1888 and then found a serum which would neutralize this toxin. In the effort to prevent diphtheria, a series of investigations was begun in 1923 by Professor Ramon at the branch Pasteur Institute in one of the suburbs of Paris. The results of fifteen years of application of this method of vaccination against diphtheria by the use of the toxoid was described in the January 21 Paris letter (THE JOURNAL, February 25, p. 758). In addition to vaccination against diphtheria, the branch Pasteur Institute under the direction of Professor Ramon has investigated the question of vaccination against tetanus. Both of these toxoids are now employed extensively in the French army.

Prof. Pasteur Vallery-Radot described the organization of branches of the Pasteur Institute in nearly all the French colonies. The first of these was erected in Tunis in 1893 and a little later one was opened in Algiers. Since then, branches

in Morocco, Madagascar, Indo-China and French West Africa have been organized. Important contributions to our knowledge of various tropical diseases have been published, so that the result of the work of these branch institutes has been a marked reduction in the incidence and mortality of tropical diseases in the French colonies.

Infectious Diseases During 1938

Twenty-two infectious diseases are compulsorily reportable under the new law. The promptitude with which most cases are reported to the health officers has made possible the early release of rather complete statistics for the year 1938.

Diphtheria again occupied first place among infectious diseases, as it has done for many years; 149,424 cases were reported. Despite the intensive antidiphtheria campaign the disease has yet to lose its epidemic character. Since children are chiefly affected, diphtheria also ranks as the most prevalent of any disease of childhood. Second to diphtheria was scarlatina, with 114,423 cases. Unlike diphtheria, scarlatina had decreased by several thousand cases as compared with 1937. Fewer new cases of tuberculosis of the lungs were reported than in the previous year (60,420 cases in 1938, 63,570 in 1937). The authors of the report emphasized, however, that a general decline in tuberculosis should not be assumed.

In contrast to the foregoing three principal infectious diseases the others appear numerically insignificant, yet if the seriousness of these less common diseases is considered their importance becomes manifest. Lupus remained virtually unchanged, 1,039 cases against 1,042 in the year 1937. On the contrary, several hundred more cases of encephalitis were reported than in 1937, bringing the total to 1,826. New cases of other infectious diseases were reported as follows: meningitis 287, poliomyelitis 5,757, typhoid 2,945, paratyphoid 3,210, dysentery 5,265, puerperal fever 2,991, febrile abortion 2,862, bite wounds inflicted by rabid animals 112, anthrax eighty-four, psittacosis thirty-seven, trichinosis twenty, malaria 365 (malaria has been compulsorily reportable since January 1), leprosy one case, in the port of Hamburg. The 1938 report mentions no cases of cholera, typhus, yellow fever, plague, variola, relapsing fever or glanders. All the foregoing have to do only with new cases. No statistics from Austria and the Sudetenland are included.

The mortality from the various disorders reflects their relative severity. In 1938 tuberculosis of the lungs caused the greatest number of deaths, 30,623. This figure is equal to numerically more than half the number of newly reported cases of the same disease. One could scarcely adduce better statistical evidence of the peril of tuberculosis than these proportional figures. In 1937, 33,236 persons died of pulmonary tuberculosis. (The tuberculosis deaths occurring in 1938 do not, of course, represent cases newly reported in that year but cases from the aggregate of tuberculous persons.) Conversely, despite the high morbidity of diphtheria there were only 5,286 deaths from that disease. This figure is even smaller than that for the year 1937, although more cases were reported in 1938. This decline in fatalities was probably due to improved treatment and diminished severity of diphtheria. Even smaller was the scarlatina mortality, 759 deaths in 114,243 cases. Among 1,826 cases of lethargic encephalitis there were 842 deaths, most of the victims being children; among 287 cases of meningitis there were 160 deaths; among 5,757 cases of typhoid, 338 deaths. Other fatalities included paratyphoid 126 deaths, dysentery 161 deaths, puerperal fever 548 deaths, febrile abortion 344 deaths, bite wounds twelve deaths, psittacosis six deaths. In general, with the exception of encephalitis, poliomyelitis, typhoid, paratyphoid and anthrax a recession in the number of fatal cases of infectious disease took place during 1938.

The "House of Health"

The national chamber of physicians in collaboration with various other officials has established a hospital on the shores of the Starnberger See near Munich, which is considered a model for all German hospitals of the future. This institution has been equipped along the lines of "new German medicine" as practiced at the Rudolf Hess Hospital, Dresden. The layout includes common dining halls, a promenade adjoining the baths, bordered by outdoor bathing pools in the kneippist tradition, lounging halls for summer and winter treatment and a spacious gymnasium. The building is surrounded by a huge park in which are facilities for individual physical exercise and for games, including a sort of common recreation area for men and women. The *raison d'être* of all these innovations is, as officially stated, a physical and mental rehabilitation of the patients, to supplement the usual hospital care. The new system will above all be directed to prevention of "diseases of civilization." The following considerations motivated foundation of the new institution: Hospital routines have heretofore been based too exclusively on the care of the patient. This has tended to make a patient "soft" and easily susceptible to psychic disturbances. Accordingly, the new establishment attempts a comprehensive program of rehabilitation which looks beyond the mere curative goal and which is designed to awaken and strengthen against the future the natural forces of resistance both physical and mental. Hence for this institution "for the cure and prevention of sickness" the name "house of health" (gesundungshaus) has been selected as more appropriate than the usual term "hospital" (krankenhaus).

ITALY

(From Our Regular Correspondent)

Feb. 28, 1939.

National Congress of Pediatricians

The Società Italiana di Pediatria recently held its sixteenth national congress at the University of Genoa.

The first topic was "Meningitis with Clear Cerebrospinal Fluid in Children." Tuberculous meningitis was excluded. Professor Taccone said that meningitis with clear cerebrospinal fluid may be primary or secondary and of bacterial or nonbacterial origin. Meningitis from a neurotropic virus and of physical, chemical or unknown origin is primary nonbacterial meningitis. The forms which develop in the course of bacterial infections from the direct or indirect action of bacteria are secondary bacterial forms, whereas those which complicate nonbacterial infections (such as so-called sympathetic meningitis and those from exogenic intoxication, anaphylaxis and the like) are secondary nonbacterial forms. Primary serous meningitis with clear cerebrospinal fluid is benign. Clinical meningeal symptoms with more or less transient and extensive paralysis are frequently caused by poliomyelitis. Meningitis from epidemic encephalitis is rare. In latent tuberculous meningitis, meningeal symptoms do not develop. The cerebrospinal fluid shows neither chemical nor cytologic changes, but it contains tubercle bacilli. In the course of benign lymphocytic acute meningitis the cerebrospinal fluid is altered. The speaker disapproved of the tendency to diagnose benign lymphocytic meningitis in the case of meningeal reactions with cerebrospinal fluid changes from which the patient recovers. The condition may be a reaction to various diseases, especially in relation to seasonal influences. The existence of a virus for benign lymphocytic meningitis has not been proved, and the autonomy of the form is as yet hypothetic. In meningitis with clear cerebrospinal fluid there are albuminosis and lymphocytosis of the cerebrospinal fluid.

Professor De Simone, the second speaker, said that secondary meningitis, bacterial or nonbacterial, may develop in the course of or at the end of certain diseases. Probably this form represents special humoral reactions of the patient or a diminished virulence of bacteria in the given infection. There are several forms of meningococcic meningitis. In the fulminant form the cerebrospinal fluid may be slightly altered because of the rapidly fatal evolution. Some forms of meningitis, including benign lymphocytic meningitis, may be due to an attenuated meningococcic infection. Other forms of secondary bacterial meningitis are those from icterohemorrhagic spirochetosis and from syphilis. The latter may develop with secondary syphilis or after administration of insufficient treatment. The speaker discussed also meningitis from trauma, sun stroke, heat stroke, simple lumbar puncture, introduction of foreign substances into the spinal canal and local anaphylactic reactions. Frequently the symptoms are not proportional to the changes in the cerebrospinal fluid.

NUTRITIONAL DISEASES IN INFANTS

The second topic was "Acute Nutritional Diseases in Infants." Professor Barberi discussed the etiology and pathogenesis of diseases of the digestive tract in infants. Infection is an important factor. Constitution plays a part because of the individual needs and assimilation by infants of certain constituents of food. Exudative diatheses are predisposing factors in the development of gastrointestinal disturbances. The climatic and meteorologic changes of summer also have a role. The administration of colloids or of acidified milk, a diet without any milk, diminution of the intake of milk and administration of greens, fruits and vitamins are of value in preventing acute nutritional disturbances in infants. Milk used in the treatment of nutritional diseases in nurslings must contain a reduced amount of fat, modified casein and a sufficient amount of carbohydrates to compensate for the deficiency of fats and to control intestinal putrefaction.

Professor Moggi pointed out the importance of breast feeding in the prevention of nutritional diseases in nurslings and the advisability of establishing a nursery room in industrial centers in order that working mothers may feed their infants. Placing infants in the homes of nurses does not give satisfactory results. It is advisable to establish periodic consultations with nurses who conduct nurslings' homes and to have legal control of them. The education of mothers about the health of infants is important, especially in the care of nutritional diseases. The courses on puericulture for mothers given every year by the Opera Nazionale per la Maternità e Infanzia and the courses in specialized pediatrics for municipal physicians given by the ministry of internal affairs have given satisfactory results.

A special session of the congress was devoted to the care of illegitimate children. The next congress will meet in Rome.

Annual Congress on Urology

The Società italiana di Urologia recently held its seventeenth national congress in Rome.

Dr. Oberholtzer of Rome spoke on the first topic, "Hormones in the Treatment of Hypertrophy of the Prostate." Theoretically two different male hormones are formed by the testicular interstitial cells. Some authors say that the testicle contains cells which produce estrogen, which exists in the normal urine of man. These substances have an effect on the size and structure of the prostate. Those from Sertoli's cells prevent hypertrophy, whereas those from the interstitial cells stimulate it. Estrogen may induce fibro-adenomatous degeneration of the posterior lobes of the prostate. Variations in the volume and structure of the prostate begin when the equilibrium between these substances, especially between androgen and estrogen, is destroyed. In the literature are reports of more than 1,000 cases of endocrine treatment of hypertrophy of the prostate. The speaker reported results in a group of 150 patients, of whom 112 were treated with androgen. The remaining patients had either estrogen or a combined treatment of androgen and estrogen. The speaker believes that glandular disturbances are the most plausible cause of prostatic hypertrophy. The treatment with androgen gives satisfactory results in many cases. The general condition of the patient and the renal functions improve, and the vesical residue diminishes or disappears completely. The treatment is valuable after intra-urethral resection to prevent recurrence. It is harmless, has no contraindications and does not interfere with the results of prostatectomy if indicated. Prostatectomy is followed by rapid recovery in patients who have had the endocrine treatment and complications are rare. Such treatment may stop the evolution of prostatic hypertrophy but does not diminish the size of the adenoma.

TRANSPLANTATION OF URETERS

The second topic, "Transplantation of Ureters," was divided into two subtopics. Professor Chiandano discussed "Ureteral Anastomoses and Ureteral Transplantations." He reviewed the operations used in performing uretero-ureteral anastomoses and in transplanting the ureters to the bladder and intestine. The end to end circular suture (Schopf's technic) is the simplest method for ureteral anastomoses. Transplantation of a ureter to the other one has not met with general approval. Cystoneostomy, or transplanting to the bladder the distal end of the ureter, does not give satisfactory results. Anastomosing a ureteral end which is provided with flaps aims to prevent stenosis at the contacting area. The technic is ingenious and stenosis does not follow. However, the best results are obtained from invagination by traction of the bladder with special instruments introduced into the bladder. Implantation of the ureter to the intestine has many advocates. The operation imitates normal conditions more closely than other operations do.

Professor Chiatellino discussed the results of experimental transplantation of the ureters in structures of the urinary tract or in the intestine. He reviewed the literature and concluded that the immediate results of ureteral transplantation have been improved by the advances in technic. Many technical refinements have been resorted to, but the results of the operation depend not only on the technic but on other factors. In further work on the subject it is advisable to take into account the part taken by physiopathologic factors in the evolution of transplanted ureters. After the presentations by the speakers and after the discussions, several other articles were read and discussed.

Marriages

MARION B. O'KELLEY, Leesburg, Fla., to Miss Barbara Davis Hoffman of Washington, D. C., Nov. 4, 1938.

ROBERT BRUCE LOGUE, Atlanta, to Miss Carolyne Frances Clements of Buena Vista in November 1938.

EDWARD CAFFRON KLEIN JR., Newark, N. J., to Miss Regina Shanley of South Orange, February 11.

RAYMOND F. SHEETS, Carthage, Ill., to Mrs. Elva McCallister in Keokuk, Iowa, February 20.

RUSSELL I. WILLIAMS, Creston, Iowa to Miss Carleen Steckelberg of Lincoln, Neb., February 25.

HAROLD WILLIAM SCHOON, Sibley, Iowa, to Miss Viola Ross of Doon in Spirit Lake, February 11.

HERMAN FRANK OPPLEMAN to Miss Gwendolyn Ann Lewis, both of Richmond, Va., January 7.

DEAN WRIGHT SMITH to Miss Dorothy C. Clark, both of Jackson, Mich., February 18.

VIRGIL O. LA FLEUR, Lorain, Ohio, to Miss Gertrude Russell of Chicago, Nov. 10, 1938.

ROSS M. ZELLER to Miss Shirley Burroughs, both of Greenville, Ohio, in January.

Deaths

Henry Schmitz ⊕ Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; American College of Medicine and Surgery, Chicago, 1906; professor and head of the department of obstetrics and gynecology, Loyola University School of Medicine; past president of the Chicago Gynecological Society; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Central Association of Obstetricians and Gynecologists, Radiological Society of North America, American College of Radiology and the American Radium Society; fellow of the American College of Surgeons; in 1930 received the gold medal of the Radiological Society of North America for achievement in the science of radiology in its application to diseases of women; in 1938 delivered the Janeway Lecture at the annual meeting of the American Radium Society, at which time he was presented with the Janeway Medal; head of the radiation therapy department and attending gynecologist, Mercy Hospital; attending gynecologist to the Cook County Hospital; consulting gynecologist to the Misericordia and Holy Cross hospitals since 1925; director of Cancer Research Institute of Chicago since 1928; secretary, board of trustees, Lewis Memorial Maternity Hospital since 1931; author of "Manual of Diseases of Women," 1912; "Handbook of Gynecology," 1915; "The Physics and Biological Principles of Radiation Therapy," 1922; contributed a chapter on "Radiology" in Davis's Gynecology and Obstetrics, 1934; aged 67; died, April 17, of lobar pneumonia.

Allen Deming Lazenby ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, 1916; one of the original members of the Council on Industrial Health of the American Medical Association; was a captain in the M. C., U. S. Army, in 1917 and retired from active duty in 1919 for disability incident to the service; served during the World War; fellow of the American College of Surgeons and the Association of Industrial Physicians and Surgeons; chairman of the Industrial Health Committee of the Medical and Chirurgical Faculty of Maryland; a member of the Medical Committee of the New York World's Fair; a director of the Baltimore Chapter of the American Red Cross; vice president and medical director of the Maryland Casualty Company; aged 45; died, April 18, of cardiovascular renal disease.

J.; St. Louis University School of Medicine, 1929; past president and secretary of the Somerset County Medical Society; formerly county coroner; on the staffs of St. Peter's Hospital, New Brunswick, Somerset Hospital, Somerville, and Muhlenberg Hospital, Plainfield; aged 45; died, January 1, of coronary thrombosis.

Walden Evermont Muns, Birmingham, Ala.; University and Bellevue Hospital Medical College, New York, 1914; formerly assistant professor of clinical medicine, New York Post-Graduate Medical School, Columbia University, New York; aged 54; died, January 31, in the Veterans Administration Facility, Tuscaloosa, of arteriosclerosis, hypertension, nephritis and uremia.

Ernst Freund, Los Angeles; Medizinische Fakultät der Universität Wien, Austria, 1926; associate professor of orthopedics, College of Medical Evangelists; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; on the staffs of the Cedars of Lebanon Hospital and White Memorial Hospital; aged 36; died, Dec. 12, 1938.

Arthur Lemuel Kennedy, Denver; Harvard University Medical School, Boston, 1901; member of the Colorado State Medical Society; assistant professor of clinical medicine and therapeutics, University of Colorado School of Medicine, 1905-1907, and assistant professor of medicine, 1907-1910; aged 72; died, January 4, in La Jolla, Calif., of bronchopneumonia.

Harris Dana Newkirk ⊕ Anaheim, Calif.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1903; fellow of American College of Surgeons; served during the World War; on the staffs of the Orange County Hospital and St. Joseph Hospital, Orange, and Fullerton (Calif.) Hospital; aged 60; died, Dec. 31, 1938.

James Otho Parramore, Crown Point, Ind.; Medical College of Virginia, Richmond, 1914; member of the Indiana State Medical Association; served during the World War; fellow of the American College of Physicians; medical director and superintendent of the Lake County Tuberculosis Sanatorium; aged 49; died, January 24, of brain tumor.

Lawrence Lloyd Purifoy ⊕ El Dorado, Ark.; Memphis (Tenn.) Hospital Medical College, 1903; Tulane University of Louisiana School of Medicine, New Orleans, 1913; fellow of the American College of Surgeons; chief of surgical staff, Henry C. Rosamond Hospital; aged 56; died, January 7, of injuries received in an automobile accident.

Washington Price Timmerman, Batesburg, S. C.; Medical College of the State of South Carolina, Charleston, 1891; member and past president of the South Carolina Medical Association; at one time mayor and member of the board of trustees of the schools of Batesburg; aged 69; died, Dec. 24, 1938, in a hospital at Columbia.

Alexander Scanlin Ross ⊕ Camden, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; fellow of the American College of Surgeons; surgeon to the Cooper Hospital and the Zurbrugg Memorial Hospital, Riverside; aged 62; died, January 11, of myocardial insufficiency and lobar pneumonia.

Stanley E. Bryant, Dowagiac, Mich.; Michigan College of Medicine and Surgery, Detroit, 1905; member of the Michigan State Medical Society; county coroner; at various times city health officer and member of the city board of health; aged 66; on the staff of the Lee Memorial Hospital, where he died, Dec. 28, 1938.

Archibald A. McLaurin, Pierre, S. D.; Rush Medical College, Chicago, 1911; member of the South Dakota State Medical Association and the Radiological Society of North America; on the staff of the Pierre Indian School Hospital; aged 62; died, January 5, of myxosarcoma testis with metastases.

William E. A. Forde, Nashville, Tenn.; Meharry Medical College, Nashville, Tenn., 1914; professor of otolaryngology at his alma mater; on the attending staff of the George W. Hubbard Hospital, where he was in charge of the otolaryngology service; aged 54; was shot and killed by a student in January.

William Alger Shaw ⊕ Reno, Nev.; Jefferson Medical College of Philadelphia, 1911; member of the American Academy of Pediatrics; served during the World War; on the staffs

of St. Mary's and Washoe General hospitals; aged 50; was found dead, January 20, of a self-inflicted bullet wound.

Daniel Louis Scanlan ⊕ Volga, S. D.; Minneapolis College of Physicians and Surgeons, 1899; past president of the South Dakota State Medical Association; medical superintendent of the Volga Hospital; fellow of the American College of Surgeons; aged 66; died in March of cerebral hemorrhage.

Russell Wesley Raynor ⊕ Pikeville, Ky.; University of Maryland School of Medicine, Baltimore, 1908; formerly acting assistant surgeon in the U. S. Public Health Service; on the staffs of the Beaver Valley Hospital, Martin, and the Methodist Hospital; aged 52; died, January 20, of pneumonia.

Peter Leo McKallagat, Lawrence, Mass.; Columbia University College of Physicians and Surgeons, 1906; member of the Massachusetts Medical Society; formerly city physician, and member of the board of health; aged 55; died, January 19, in Miami Beach, Fla., of coronary occlusion.

John Monroe McSparin, Carriers Mills, Ill.; Loyola University School of Medicine, Chicago, 1916; served during the World War; for many years member of the board of education; aged 49; died, January 7, of chronic myocarditis, nephritis, hypertension and pulmonary tuberculosis.

George C. Nix, Opp, Ala.; University of Texas School of Medicine, Galveston, 1904; member of the Medical Association of the State of Alabama; at one time member of the board of education; formerly county health officer and postmaster; aged 60; died in January of pneumonia.

Theophilus E. Hinshaw, Winfield, Kan.; Missouri Medical College, St. Louis, 1882; member of the Kansas Medical Society; on the staff of the State Training School; trustee of the Southwestern College for many years; aged 80; died, Dec. 23, 1938, in St. Mary's Hospital.

Claude Murphy Scarborough ⊕ Chicago Heights, Ill.; Northwestern University Medical School, Chicago, 1926; aged 39; on the staffs of St. James Hospital, Chicago Heights and Ingalls Memorial Hospital, Harvey, where he died, January 18, of coronary thrombosis.

Jacob E. K. Morris ⊕ Olean, N. Y.; University of Buffalo School of Medicine, 1879; fellow of the American College of Surgeons; aged 82; on the staff of the Olean General Hospital; died, January 23, of chronic nephritis, hypostatic pneumonia and streptococcic sore throat.

Edward Adams Romig, Newberg, Ore.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877; veteran of the Spanish-American War; aged 86; died, January 26, in the Veterans Administration Facility, Portland, of cerebral hemorrhage.

William Harvey McLean ⊕ Lexington, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1920; fellow of the American College of Surgeons; on the staff of the Good Samaritan Hospital; aged 45; died, January 13, of arteriosclerotic heart disease.

Michael Joseph Purcell ⊕ Chicago; Chicago College of Medicine and Surgery, 1912; fellow of the American College of Surgeons; on the staffs of St. Joseph's Hospital and the John B. Murphy Hospital; aged 60; died, January 2, of arteriosclerotic heart disease.

Alvin Lebrun Nourse, Anniston, Ala.; Beach Medical Institute, Indianapolis, 1885; Gate City Medical College, Dallas, 1907; member of the Medical Association of the State of Alabama; died, January 12, of pneumonia following fracture of the hip received in a fall.

James Blaine Muncy ⊕ Pennington Gap, Va.; Medical College of Virginia, Richmond, 1918; past president and secretary of the Lee County Medical Society; served during the World War; aged 45; died suddenly, January 20, of a self-inflicted wound.

Claude Bernard Calbreath, Hastings, Neb.; Keokuk (Iowa) Medical College, 1898; member of the Nebraska State Medical Association; served during the World War; aged 60; died, January 9, at the Mary Lanning Hospital of carcinoma of the esophagus.

Robert A. Hudson, Islandton, S. C.; Medical College of the State of South Carolina, Charleston, 1909; member of the South Carolina Medical Association; postmaster; aged 52; died, January 21, in the Charles Es-Dorn Hospital, Walterboro, of coronary thrombosis.

George Gill Mulherin, Brownsville, Tenn. (licensed in Tennessee in 1904); member of the Tennessee State Medical Association; aged 60; on the staff of the Haywood County Memorial Hospital, where he died, January 9, of influenza and pneumonia.

Heinrich F. W. Petersen, Dundee, Ill.; College of Physicians and Surgeons of Chicago, 1888; member of the Illinois State Medical Society; aged 84; died, January 30, in a hospital at Elgin of cerebral arteriosclerosis, myocarditis and bronchopneumonia.

Thaddeus Kosciusko Jones, Henrietta, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; served during the World War; for many years mayor; county health officer; aged 62; died, January 24, of myocarditis and toxic goiter.

Charles Epley Patterson, Fayette, Ohio; Starling Medical College, Columbus, 1896; member of the Ohio State Medical Association; at various times member of the village council, and mayor; aged 65; died, January 3, of coronary thrombosis.

Henry Kruse, Chicago; Loyola University School of Medicine, Chicago, 1916; member of the Illinois State Medical Society; aged 53; died suddenly, January 7, in the Roseland Community Hospital of cerebral hemorrhage and hypertension.

George Thomas Magraw, Avondale, Pa.; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 71; died, January 9, of cardiovascular renal disease.

William Porter Logue, Williamsport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; aged 75; died, January 5, of chronic myocardial fibrosis.

Matthew Joseph Shields, Scranton, Pa.; University of the City of New York Medical Department, 1888; founder of the American Red Cross first aid work; served during the World War; aged 76; died, January 23, of chronic myocarditis.

Theodore Anthony Kreuser, Hines, Ill.; Rush Medical College, Chicago, 1897; member of the Illinois State Medical Society; aged 73; died, January 8, at the Veterans Administration Facility of arteriosclerosis and cardiac hypertrophy.

Andrew Pleasant Bush, Columbia, Tenn.; Jenner Medical College, Chicago, 1913; Kansas City (Mo.) College of Medicine and Surgery, 1920; aged 57; died, January 9, in the Baptist Hospital, Memphis, of myocardial insufficiency.

Freeda May Piles Clark, Chambers, Neb.; Hahnemann Medical College and Hospital, Chicago, 1899; aged 65; died, January 27, in the Nicholas Senn Hospital, Omaha, of gastric ulcer, carcinoma and postoperative pneumonia.

Marcus Claude Roberts ⊕ Hutchinson, Kan.; Northwestern University Medical School, Chicago, 1906; on the staffs of the Grace Hospital and St. Elizabeth Mercy Hospital; aged 60; died, January 6, of coronary thrombosis.

John Adam Parker, Kansas City, Mo.; Hahnemann Medical College of the Kansas City University, Kansas City, Mo., 1902; Kansas City Hahnemann Medical College, 1906; aged 64; died, January 1, of heart disease.

Louis King, Chicago; St. Louis College of Physicians and Surgeons, 1900; member of the Illinois State Medical Society; aged 63; died, January 9, of hemopericardium, ruptured cardiac infarct and coronary sclerosis.

Raymond Erastus Gaston ⊕ Cincinnati; Miami Medical College, Cincinnati, 1905; served during the World War; on the staffs of the Christ and St. Francis hospitals; aged 62; died, January 3, of myocarditis.

Henry P. Kohberger, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1902; aged 59; on the staff of St. Joseph's Hospital, where he died, January 3, of coronary thrombosis.

Richard Z. Query, Charlotte, N. C.; University College of Medicine, Richmond, 1907; aged 58; died, January 7, in the Presbyterian Hospital of cerebral hemorrhage and hypertensive cardiovascular disease.

Michael Ritter Miley, Beecher, Ill.; Rush Medical College, Chicago, 1896; member of the school board for many years; formerly mayor; aged 80; died in January of arteriosclerosis and heart disease.

Ernest Foucher, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1911; aged 52; died, January 11, of pneumonia.

Justus Sinexon, Philadelphia; Jefferson Medical College of Philadelphia, 1883; formerly on the staffs of the Charity, Jefferson and Presbyterian hospitals; aged 77; died, Dec. 27, 1938, of lobar pneumonia.

Frank Morris ⊕ Lima, Ohio; Starling Medical College, Columbus, 1892; on the staffs of St. Rita's and Memorial hospitals; aged 70; died, January 25, of myocarditis, coronary disease and uremia.

Robert E. Fivey, Chicago; Albany (N. Y.) Medical College, 1887; medical director of the Globe Insurance Company; aged 73; died, March 11, in the Evangelical Deaconess Hospital.

William Edgar Robertson, Milton, Ont., Canada; University of Toronto Faculty of Medicine, 1900; formerly a medical missionary; aged 59; died, January 15, of heart disease.

William K. Nisbet ⊕ Earlington, Ky.; University of Louisville (Ky.) Medical Department, 1888; served during the World War; aged 71; died, January 13, of carcinoma of the stomach.

George Ringel, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1901; aged 58; died, January 3, in the Menorah Hospital, of coronary occlusion and arteriosclerosis.

James F. Lewis, Dupont, Ind.; Medical College of Ohio, Cincinnati, 1875; aged 82; died, January 4, of hypostatic pneumonia, hypertrophy of the prostate and epithelioma of the face.

Michael D. Kiely, Archer, Iowa; University of Edinburgh Faculty of Medicine, Scotland, 1885; formerly mayor; aged 78; died, January 9, in Sioux City of coronary disease.

Mark Edward Johnson, Corning, Iowa; Jefferson Medical College of Philadelphia, 1895; member of the Iowa State Medical Society; aged 77; died, January 9, of coronary occlusion.

Robert C. Hutcheson, Elk Falls, Kan.; Kansas City Medical College, 1885; member of the Kansas Medical Society; aged 80; died, January 5, of carcinoma of the stomach and liver.

Margaret Packer Forcee Kuyk ⊕ Richmond, Va.; Woman's Medical College of Pennsylvania, Philadelphia, 1891; aged 78; died, January 16, of cardiovascular renal disease.

Richard Homer Fitch, Sturgis, S. D.; Washington University School of Medicine, St. Louis, 1937; aged 35; died, January 7, in Sioux City, Iowa, of coronary occlusion.

Charles Andrew Kenner, Omaha; Rush Medical College, Chicago, 1883; aged 77; died, January 23, of bronchopneumonia following an injury received in a fall down the stairs.

Otto James Schwer, St. Louis; Barnes Medical College, St. Louis, 1907; member of the Missouri State Medical Association; aged 68; died, January 9, of diabetes mellitus.

Helen Kirshbaum, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1893; aged 66; died, January 22, in the Mount Sinai Hospital of coronary thrombosis.

Charles Clinton Parker Jr., ⊕ Boston; Tufts College Medical School, Boston, 1918; served during the World War; aged 45; died in January of illuminating gas poisoning.

Stuart M. Mann, Moyock, N. C.; College of Physicians and Surgeons, Baltimore, 1895; aged 64; died, January 25, in a hospital at Norfolk, Va., of coronary occlusion.

Henry Williams Hall, Winston-Salem, N. C.; Meharry Medical College, Nashville, Tenn., 1918; aged 43; died, January 7, of an incised wound of the throat, self inflicted.

Charles E. Pugh ⊕ Chicago; Rush Medical College, Chicago, 1891; aged 73; died, January 18, in the Berwyn (Ill.) Hospital of a skull fracture received in a fall.

Seaborn Wesley Owens, Ashland, Ala. (licensed in Alabama in 1887); aged 85; died, January 4, in St. Luke's Hospital at Jacksonville, Fla., of cerebral hemorrhage.

Burtis W. McLean ⊕ Jenks, Okla.; College of Physicians and Surgeons, Baltimore, 1906; aged 63; died, January 23, of injuries received in an automobile accident.

Charles Mellies, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1884; aged 79; died, January 31, of arteriosclerosis and coronary thrombosis.

Irvine Leland Nowlan, South Amherst, Mass.; Dartmouth Medical School, Hanover, N. H., 1894; aged 68; died, January 14, in Northampton of arteriosclerosis.

Lee Anderson Richmond, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1909; aged 54; died, January 16, of heart disease.

George F. Roby, Minneapolis; Hahnemann Medical College of Philadelphia, 1881; aged 79; died, January 4, in St. Barnabas Hospital of arteriosclerosis.

Walter Preston Perkins, Girvin, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1888; aged 84; died, January 26, of pneumonia.

Paul John Love, Greensboro, N. C.; Eclectic Medical College, Cincinnati, 1922; aged 41; died, January 5, of chronic myocarditis and coronary occlusion.

Willis H. Haviland, Butte, Mont.; New York Homeopathic Medical College and Hospital, New York, 1888; aged 74; died, January 15, of chronic endocarditis.

John M. C. McAllister, Rochelle, Ga.; University of Georgia Medical Department, Augusta, 1902; aged 59; died, January 25, of coronary occlusion.

Benjamin F. Moreland, Shults, Okla.; University of Arkansas School of Medicine, Little Rock, 1912; aged 69; died, January 16, of Hodgkin's disease.

Samuel Marcus Oppenheim, Denver; Denver and Gross College of Medicine, 1904; aged 55; was found dead, January 4, of an overdose of narcotics.

Barney Ellsworth Crosby, Palo Alto, Calif.; University of Oregon Medical School, Portland, 1893; aged 77; died, January 2, of Parkinson's disease.

Louis Hamilton Seth ⊕ Wittman, Md.; University of Maryland School of Medicine, Baltimore, 1908; aged 55; died, Dec. 25, 1938, of heart disease.

Monroe Hinson Tunnell ⊕ Bryn Mawr, Pa.; Jefferson Medical College of Philadelphia, 1912; aged 52; died, Dec. 12, 1938, of chronic heart disease.

Thomas John Allen, Tacoma, Wash.; American Medical Missionary College, 1899; aged 69; died, January 1, of coronary occlusion and arteriosclerosis.

Samuel Purdy [illegible] Francisco; California Eclectic Medical [illegible] 1900; aged 72; died, Dec. 9, 1938, of heart disease.

George R. Mitchell, Madison, Wis.; Detroit Homeopathic Medical College, 1872; Civil War veteran; aged 90; died, Dec. 31, 1938, of general debility.

Fred Ferdinand Fair, Chicago; Northwestern University Medical School, Chicago, 1905; aged 55; died, Dec. 30, 1938, of cardiovascular renal disease.

Abram Ashley Wilson ⊕ Davis, Ill.; Northwestern University Medical School, Chicago, 1894; aged 68; died, Dec. 11, 1938, of coronary occlusion.

Gordon Edgar Mordoff, Wilmette, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1907; aged 56; was shot and killed, January 11.

Harry Lyman Grazier, Aliquippa, Pa.; University of Pittsburgh School of Medicine, 1912; aged 54; died, Dec. 23, 1938, of myocarditis and influenza.

Andrew Gilbert Belsheim, Guler, Wash.; State University of Iowa College of Medicine, Iowa City, 1901; aged 64; died, Dec. 21, 1938, of pleurisy.

Harmon L. Pippin, Bristol, Va.; University College of Medicine, Richmond, 1902; aged 60; was killed, January 8, when struck by a train.

Daniel W. Mears, Scranton, Pa.; Jefferson Medical College of Philadelphia, 1885; on the staff of the State Hospital; aged 79; died, Nov. 12, 1938.

Joseph N. Daniels, Milwaukee; Hahnemann Medical College and Hospital, Chicago, 1886; aged 88; died, Dec. 5, 1938, of cerebral hemorrhage.

Eugene G. Lester, Madisonville, Ky.; Meharry Medical College, Nashville, Tenn., 1915; aged 58; died, Dec. 26, 1938, of cardiorenal disease.

Henry Burr Cogswell, New York; Bellevue Hospital Medical College, New York, 1886; aged 77; died, January 5, of coronary thrombosis.

Jerome C. McNees, Ardmore, Okla.; Missouri Medical College, St. Louis, 1885; aged 76; died, Dec. 14, 1938, of carcinoma of the liver.

Henry Joseph Bell, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; aged 76; died, Nov. 16, 1938, of angina pectoris.

Frederick Poppe, Pulcifer, Wis. (licensed in Wisconsin in 1899); for many years postmaster; aged 88; died, Dec. 30, 1938, of senility.

James R. Steele, Danville, Ky.; St. Louis College of Physicians and Surgeons, 1893; aged 70; died, Dec. 13, 1938, of heart disease.

Winston Decatur Coates, San Jose, Calif.; California Medical College, San Francisco, 1896; aged 80; died, January 4, of pneumonia.

Willis Henry Faulkner, Garrison, Texas; Maryland Medical College, Baltimore, 1905; aged 67; died in January of pneumonia.

James M. Elliott, Ogden, Utah; Missouri Medical College, St. Louis, 1886; aged 83; died, Dec. 27, 1938, of chronic myocarditis.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE—The abstracts that follow are given in the briefest possible form. (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition; (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration]

Akalyn—Medical Products Co, and Akalyn Co, New Orleans Composition Essentially acetophenetidin (3 2 grains per tablet), sodium salicylate (2 grains per tablet), magnesium oxide, starch, talc and red coloring Misbranded because quantity or proportion of acetophenetidin present was not declared, as required by law, misbranded, further, because fraudulently represented as a remedy for all forms of pain arising from headaches, neuralgia, rheumatism, menstrual troubles, etc—[*N J 27503, January 1938*]

Anbesol—Anbesol Co, Newark, N J Composition Essentially alcohol, glycerin, water, benzocaine, menthol, camphor and small amounts of free and combined iodine and a substance resembling carbolic acid Fraudulently represented as producing immediate local anesthesia, killing germs, and promptly relieving pain, abscesses, inflammation, fever, sores, etc—[*N J 27898, April 1938*]

Anti-Pain Liniment—Strong, Cobb & Co, Inc, Cleveland Composition Essentially oils of wintergreen eucalyptus and turpentine, in a petrolatum base Fraudulently represented as a remedy for neuralgic pains, rheumatism, sore throat, etc—[*N J 27717, April 1938*]

Athlo Ointment and Athlo Tablets—Athlophoros Co, Pomfret Center, Conn Composition Ointment essentially menthol, thymol, camphor, wintergreen, and oils of mustard and turpentine, in an ointment base, tablets, essentially aloin, strychnine and compounds of iron, arsenic, mercury and iodine Ointment fraudulently represented as a remedy for inflammations, croup, etc, the tablets as effective in treating indigestion, liver disorders, general debility, gout, stomach trouble and chronic diseases—[*N J 27923, April 1938*]

Bull's (W H) Quick Pile Relief—W H Bull Medicine Co, Inc, St Louis Composition Essentially pine tar and small amounts of carbolic and tannic acids in a petrolatum base Not antiseptic, as represented Fraudulent therapeutic claims—[*N J 27546, January 1938*]

Cas-Tro-Ma—Dixie Medicine Co, McMinnville, Tenn Composition Essentially water, glycerin, sodium salicylate, and extracts of laxative plant drugs For stomach troubles, sick headache, cramps, colic, etc Fraudulent therapeutic claims—[*N J 27887, April 1938*]

Cereal Lactic—Cereal Lactic Co, Woodward, Iowa Examination of different specimens showed they contained viable lactic acid producing bacteria ranging from 370,000 to 2,000,000 per gram of dry material, thus falling far below the professed standard under which the product was sold. Fraudulently represented as an effective treatment of stomach and intestinal disorders, high blood pressure, nervous symptoms, arthritis, neuritis, eczema, etc—[*N J 27548, January 1938*]

Clydesdale Ointment—George W Bicknell Co, Pittsburgh Composition Essentially petrolatum, with a small amount of volatile oils including turpentine and a safrol containing oil Fraudulently represented as a cure for hemorrhoids, skin trouble, rheumatism, corns, sore throat, etc—[*N J 27921, April 1938*]

Corona Wool Fat Compound—Corona Mfg Co, Kenton, Ohio Composition Essentially hydrous wool fat containing a small amount of common salt, and perfumed with oil of wintergreen Fraudulently represented as a remedy for sores, boils, wounds, etc—[*N J 27720, April 1938*]

Count's Kill Germ—Count's Chemical Co, Nashville, Tenn Composition Essentially mineral oil, with small amounts of pine needle oil and water Not an antiseptic or germicide, as represented For rheumatism, asthma, indigestion, bad blood, erysipelas, "piles," etc. Fraudulent therapeutic claims—[*N J 27727, April 1938*]

Dodds (Dr) Purgolax Tablets—Southwestern Chemical Co, Jonesboro, Ark Composition Essentially phenolphthalein, calomel and laxative plant drugs, such as aloe, coated with chalk, sugar and a pink coloring material Fraudulently represented as a remedy for autointoxication, constipation, and certain forms of biliousness—[*N J 27568, January 1938*]

Duray—Duray Laboratories, Inc, Seattle Composition Essentially borax, with small amounts of boric and carbolic acids, menthol and a blue pigment Fraudulently represented as a remedy for female disorders, an aid to the menopause, and a germicide—[*N J 27558, January 1938*]

Effervescent Seltzer.—Honoroff Laboratories, Inc, Chicago Composition Essentially baking soda, citric and tartaric acids with 1 2 per cent of acetanilid (5 grains per ounce), 2 8 per cent of sodium bromide, and caffeine For stomach disorders and after-effects of excessive eating or drinking Fraudulent therapeutic claims—[*N J 27567, January 1938*]

Elder Flower Eye Lotion—George B Evans Laboratories, Inc, Philadelphia Composition Essentially a dilute solution of boric acid and common salt, with a small amount of alcohol and lesser quantities of plant extractives including camphor, peppermint, cherry laurel and elder flowers Falsely represented as being essentially elder flower, peppermint, witch hazel, cherry laurel and camphor, fraudulent therapeutic claims—[*N J. 27884, April 1938*]

Elixir Tussinol—Medicinal Research Laboratories, Philadelphia Composition Essentially a solution of gold bromide Fraudulently represented as a remedy for whooping cough and other spasmodic coughs—[*N J 27563, January 1938*]

Eupraxine Eczema Salve and Eupraxine Wound Salve—Eupraxine Co, Detroit Composition The first named was essentially zinc stearate and boric acid, in petrolatum, and the second was essentially ichthammol and petrolatum Fraudulent therapeutic claims—[*N J 27907, April 1938*]

Fairey Oil—Fairey Wholesale Drug Co, Inc, Orangeburg S C Composition Essentially oils of wintergreen and turpentine, and a green coloring material Fraudulently represented as a remedy for neuralgia, rheumatism, cramps, insect bites, etc—[*N J 27551 January 1938*]

Filkins' (J L) Wonderful Wintergreen—J L Filkins & Co, Yonkers, N Y Composition Essentially potassium iodide (2 5 per cent), alcohol and water, with extracts of plant drugs including colchicum, flavored with wintergreen Fraudulently represented as a remedy for various forms of rheumatism—[*N J 27922, April 1938*]

Flame Liniment—G F Foster Products Co, St Paul, Minn Composition Essentially a petroleum oil, with small amounts of volatile oils including mustard, wintergreen and cinnamon, colored with a red dye Fraudulently represented to kill pain and relieve rheumatism, stiff neck, lame back and aching joints—[*N J 27890, April 1938*]

Goody's Headache Powder—Goody's, Inc, Winston Salem, N C Composition Chiefly acetanilid, though each tablet contained less than the 4 grains claimed, hence adulterated Misbranded because falsely represented as safe and reliable, and as containing no narcotics—[*N J 27925 April 1938*]

Grandma's Dia-Col—Park Laboratory Co, Inc, San Antonio, Texas Composition Essentially extracts of plant drugs, with small amounts of camphor, menthol and red peper, alcohol (28 per cent by volume), glycerin and water Fraudulently represented as a remedy for colic, diarrhea, cramps, etc—[*N J 27731, April 1938*]

Heinrich's Dermo Carbo Salve—Heinrich Chemical Co, Minneapolis Composition Essentially a small amount of carbolic acid in a petrolatum base Fraudulently represented as an effective treatment for sores, cuts and wounds—[*N J 27746, April 1938*]

Heinrich's Pain-A-Way—Heinrich Chemical Co, Minneapolis Composition Chiefly water, alcohol and oils of mustard and cinnamon Fraudulently represented as a cure for cramp pains, colic, diarrhea, rheumatic pains and aching joints—[*N J 27747, April 1938*]

Heinrich's Medicated Ointment—Heinrich Chemical Co, Minneapolis Composition Camphor, oil of eucalyptus, and a very small amount of zinc oxide Fraudulently represented as a healing and penetrative treatment for all skin affections and injuries—[*N. J 27747, April 1938*]

Heinrich's Rheumatism Remedy—Heinrich Chemical Co, Minneapolis Composition Essentially a watery alcoholic solution of sodium salicylate, sugar, and a small amount of plant extractives Fraudulent therapeutic claims—[*N. J 27747, April 1938*]

Heinrich's San-I-Cide—Heinrich Co, Minneapolis Composition Alcohol, water, zinc chloride menthol aromatics and traces of formaldehyde Misbranded because alcohol content was not over 2 6 per cent by volume, whereas labels represented it to be approximately 12 per cent Fraudulently represented as a cure for bleeding gums, sore throat, tonsilitis, wounds, etc—[*N J 27747, April 1938*]

Helm's Jen-A-Rub—Helm Co, Benton Harbor, Mich Composition Essentially oil of wintergreen and menthol, in a petrolatum base For chest colds, sinus trouble, sore throat, influenza, pneumonia neuritis, etc Fraudulent therapeutic claims—[*N J 27566 January 1938*]

Hessel's Oil de Vita Salve—Vita Laboratories, Philadelphia Composition About 20 per cent of peppermint oil in an oily base, apparently petrolatum Fraudulently represented to relieve eczema and other skin eruptions, and rheumatism—[*N J 27702, April 1938*]

Histosan—Histosan Inc, New York Composition Essentially sugar, water, alcohol and small amounts of guaiacol, ammonium chloride, common salt, Glauber's salt and protein material Fraudulently represented as a remedy for colds and kindred disorders—[*N J 27723, April 1938*]

Isaac's (Dr) Big Jim—Tampa Drug Co, Tampa, Fla Composition Essentially potassium iodide (52 grains per fluidounce), alcohol, water and plant drug extracts Fraudulently represented to cure impure blood, boils, sores, rheumatism, etc—[*N J 27725, April 1938*]

Isaac's (Dr) Big Jim Healing Fluid (or Liquid)—Tampa Drug Co, Tampa, Fla Composition A watery solution containing about 6 per cent of mercuric chloride Fraudulently represented as an efficacious sore wash—[*N J 27725 April 1938*]

La-Vim—Lewis Laboratories, Inc, Atlanta Composition Essentially plant drugs including a laxative, and nux vomica, a phosphorus compound sugar alcohol and water, with cinnamon flavor Fraudulently represented as a "tonic" to correct malnutrition languor and frailty in persons of all ages—[*N J 27573, January 1938*]

Little Wonder Page's Inhalers (Cigarets)—Consolidated Chemical Co, Grand Rapids, Mich Composition Essentially plant material chiefly stramonium leaves For asthma, hay fever, catarrh bronchitis and hoarseness Fraudulent therapeutic claims—[*N J 27715, April 1938*]

Lund's Magic of the Grape—Lund's Grape Juice Co, Erie, Pa Not pure grape juice, as represented, as it was diluted and contained added grape sugar Fraudulently represented as a cure for colds, stomach, liver, kidney, lung and bladder troubles, rheumatism, etc—[*N J 27569, January 1938*]

M F C Chill and Malaria Tonic—Southwestern Chemical Co, Jonesboro, Ark Composition Essentially sugar, water, cinchonine, phenol phthalein, an iron compound, benzoic acid and extracts of plant materials Adulterated and misbranded in that it did not contain either quinine or quinidine as presented "Tonic" Fraudulent therapeutic claims—[*N J 27568, January 1938*]

Migro-Powder—C J Czarnecki, Detroit Composition Essentially baking soda and milk sugar, with 4 3 grains of acetanilid in each powder Misleadingly labeled as containing 6 grains of acetanilid per powder, fraudulently represented as a remedy for neuralgia and la grippe—[*N J 27713, April 1938*]

Miller's (Dr) Tonic Prescription—International Research Laboratory, Chicago Composition Essentially water, sugar, alcohol and extracts of plant drugs, including a laxative one Fraudulently represented as a system cleanser and a remedy for sick headache, insomnia stomach ulcers, high blood pressure, rheumatism, anemia, etc—[*N J 27714, April 1938*]

Mimeln Laxative-Aspirin—Miller Medicals Inc, Indianapolis Composition Essentially, in each tablet, 1 grain of acetanilid, 1/10 grain of aspirin, with plant drugs including caffeine, cascara sagrada and aloin Misbranded in falsely intimating that the product was chiefly aspirin, and in failing to declare the amount of acetanilid present Fraudulently represented to possess the efficacy of aspirin—[*N J 27719, April 1938*]

Monitol Bath Treatment—H A Montgomery Co, Detroit Composition Essentially water and an ichthammol like material Fraudulently represented to relieve pains of arthritis, rheumatism, sciatica and lumbago—[*N J 27722, April 1938*]

Needham's Red Clover Extract—D Needham's Sons, Chicago Composition Essentially plant materials whose ash was chiefly calcium, magnesium, potassium, sodium and iron phosphates chlorides and sulfates Fraudulently represented as effective for constipation abnormal tissue changes, carbuncles stomach troubles, mouth and throat disorders, etc—[*N J 27743, April 1938*]

Odo-Go—National Products Co, Fort Worth, Texas Composition Essentially sodium carbonate, with a small amount of potassium permanganate Misbranded because not a disinfectant, antiseptic or germicide, when used as directed Fraudulently represented as a cure for skin eruptions dandruff, sore throat, ulcers, etc—[*N J 27878, April 1938*]

Orlax Compound Tablets—G Knewitz, East St Louis, Ill Composition Essentially phenolphthalein (about 3/4 grain per tablet) and extracts of plant material including aloe, strychnine and croton oil Fraudulently represented as a tonic and preventive of constipation—[*N J 27572, January 1938*]

Phillips' Croup and Pneumonia Salve—Phillips Products Co, Watertown, Tenn Composition Essentially oils of eucalyptus and pine, in petrolatum Fraudulently represented as a cure for chest troubles—[*N J 27885 April 1938*]

Prieto Tonic—Indian Laboratory Co, Laredo Texas Composition Essentially water, glycerin alcohol, potassium iodide (about 9 grains per fluidounce) sodium benzoate, and extracts of plant drugs including cinchona Fraudulently represented as an effective general alterative tonic, aperitif, nerve sedative, blood purifier and remedy for skin diseases, anemia, etc—[*N J 27740, April 1938*]

Q E D Mineral Water—Q E D Mineral Water Co, Shakopee, Minn Composition Essentially water containing sulfur dioxide Falsely represented as a mineral water or mineral water synthetic, and a new discovery For use on open wounds, burns cuts, and as a nose and throat spray for colds and catarrh Fraudulent therapeutic claims—[*N J 27894 April 1938*]

Rel-Ka-Sol—Rel Ka Sol Chemical Co, Philadelphia Composition Essentially water, alcohol, borax and a small amount of carbolic acid For cuts burns abscesses, boils tonsilitis, blood poison, etc Fraudulent therapeutic claims—[*N J 27892, April 1938*]

Reliable Perio Pills—Rex Drug Co and Reliable Medical Co, Chicago Composition Brown tablets, essentially compounds of sodium and iron, sulfates carbonates and aloe, coated with chalk, pink tablets, essentially phenolphthalein and ginger, with sugar and chalk For menstrual irregularities Fraudulent therapeutic claims—[*N J 27912 April 1938*]

Rex Improved Hygienic Powder—Rex Drug Co, and Reliable Medical Co, Chicago Composition Essentially boric acid (99 2 per cent) and a small amount of thymol For leucorrhea, gonorrhea, etc Fraudulent therapeutic claims—[*N J 27912, April 1938*]

Rex Pep-Tone Pills—Rex Drug Co, and Reliable Medical Co, Chicago Composition Essentially iron and sodium, sulfates, carbonates and zinc phosphide, coated with chalk Fraudulently represented as a 'tonic and blood and nerve builder—[*N J 27912 April 1938*]

Ru-Ma—Dr Leonhardt Co, Buffalo Composition Essentially an aqueous solution of iodides, salicylates, acetates and a laxative plant drug For rheumatoid conditions, gouty diathesis, etc Fraudulent therapeutic claims—[*N J 27739, April 1938*]

Sal-I-Can—Dr J L Davis, Irvine, Ky Composition Essentially salicylic acid, alcohol, acetone and water *Fraudulently represented as an* effective treatment for ringworm, infected wounds, tumors, eczema, etc—[*N J 27738, April 1938*]

Sharpsteen's (Dr) Hindoo Salve No 16—Drs H & V Sharpsteen Marshall, Mich Composition Essentially small amounts of chloroform and volatile oils including sassafras and cloves, in a fatty base Misbranded because not labeled as to quantity or proportion of chloroform present, fraudulently represented as a remedy for pneumonia, piles constipation, kidney and liver disorders, eczema, etc—[*N J 27712, April 1938*]

Sharpsteen's (Dr) Vegetable Hindoo Oil No 5—Drs H & V Sharpsteen, Marshall, Mich Composition Essentially saponifiable and volatile oils including those of sassafras, cloves, menthol and camphor, with chloroform (15 per cent by volume) Falsely represented as being wholly a vegetable oil, which it was not, recommended for dyspepsia, gallstones dropsy, appendicitis, rheumatism, tuberculosis, etc Fraudulent therapeutic claims—[*N J 27712, April 1938*]

Sharpsteen's (Dr) Vegetable Tablets Nos 1, 2, 3 and 4—Drs H & V Sharpsteen, Marshall, Mich Composition "No 1," calcium and ferrous (iron) carbonates, potassium and sodium sulfates, and plant drugs including a strychnine bearing drug and a laxative one, 'No 2,' magnesium and calcium carbonates and plant drugs, including a strychnine bearing drug and a laxative one, "No 3," ferrous (iron), magnesium and calcium carbonates, and plant drugs, including quinine and a laxative one, "No 4," calcium carbonate and plant drugs, including a laxative one All fraudulently represented as remedies for stomach liver and blood diseases, different forms of rheumatism, tonsillitis, catarrh, pneumonia, erysipelas, etc—[*N J 27712, April 1938*]

Shiloh—S C Wells & Co, LeRoy, N Y Composition Essentially *terpin hydrate, tar oil, and volatile oils including peppermint, with chloroform*, glycerin and water Fraudulently represented as a remedy for coughs, angina, croup, and all pulmonary diseases including tuberculosis—[*N J 27539, January 1938*]

Simba—G F Foster Products Co, St Paul Composition A dark turbid, watery alcoholic solution of plant material, epsom salt, sodium salicylate, and an emodin bearing drug Fraudulently represented as a cure for stomach, liver, kidney and blood disorders caused by constipation autointoxication and improper digestion Further misbranded in being represented as consisting wholly of roots and herbs—[*N J 27749, April 1938*]

Si-Noze—Si Noze Products Chicago Composition Essentially benzocaine, ephedrine, camphor and menthol, dissolved in a mixture of mineral matter and fatty oil For sinus troubles, hay fever, catarrh, etc Fraudulent therapeutic claims—[*N J 27718, April 1938*]

Sitroux-Aids—Sterilak Co, Inc, Utica, N Y Composition Tissue paper containing small amounts of menthol and essential oils, such as cedar and eucalyptus For hay fever, sinus disorders, etc Fraudulent therapeutic claims—[*N J 27734, April 1938*]

Skoot—Skoot Co, Hamilton, Ohio Composition Essentially wintergreen, menthol, water and a gum For pains of rheumatism, lumbago pleurisy, headache, congestion, etc Fraudulent therapeutic claims—[*N J 27886, April 1938*]

Snipes' Japicura Skin Remedy—*Snipes Medicine Co*, Little Rock Ark Composition Essentially carbolic acid (17 per cent by weight), glycerin, sassafras oil menthol and salicylic acid Not a germicide, as represented Claims for its curative effects were fraudulent—[*N J 27395 December 1937*]

Snuffly—Vita Laboratories, Philadelphia Composition Eucalyptus oil For sinus trouble asthma hay fever, etc Fraudulent therapeutic claims—[*N J 27702, April 1938*]

Sun-Ray Vita-Lax—Vita Lax Products Co, Birmingham Ala Composition Essentially bran, agar agar, psyllium seed yeast and phenolphthalein (about 0 3 grain per average level teaspoonful) *Misbranded* because represented as a vitamin laxative, whereas it was essentially a phenolphthalein laxative Fraudulently represented as a remedy for acid indigestion deficiency diseases, rheumatism, obesity, etc—[*N J 27750, April 1938*]

Ter-O-Sul—National Hygienic Corporation, Brooklyn *Composition* Essentially starch, sodium bisulfate, baking soda, noncolloidal sulfur (7 4 per cent), and a trace of other inorganic compounds Misbranded because it contained not more than a trace of colloidal sulfur, if any and because fraudulently represented as a treatment for arthritis, sciatica, neuritis gout, skin eruptions impure blood, etc—[*N J 27742, April 1938*]

Trask's Treatment for Constipation—Western Laboratories Inc Chicago Composition Essentially plant drugs, phenolphthalein and strychnine, coated with chalk and an iron compound Fraudulent therapeutic claims—[*N J 27910, April 1938*]

Trents Eucalyptol Compound—John J Samuels, Chicago Composition Essentially water, sugar, gum and small amounts of eucalyptol and menthol Fraudulently represented as a cure for throat and lung affections—[*N J 27732, April 1938*]

Van Ogden Wonderful Liniment—Van Ogden, Inc, Chicago Composition Essentially small amounts of wintergreen menthol, red pepper, camphor, chloroform (7 minims per fluid ounce), and mineral oil Fraudulent therapeutic claims—[*N J 27910, April 1938*]

Van's Magic Oil—Guy S Venderlinde, Muskegon Mich Composition Essentially volatile oils (10 per cent) including those of camphor and eucalyptol, in a base of linseed oil Fraudulently represented as a remedy for inflammatory diseases, rheumatism, hemorrhoids, toothache, etc—[*N J 27915 April 1938*]

Vapor Balm (Anti-Pain Ointment)—Specialized Laboratory, Buffalo *Composition Essentially oil of wintergreen*, menthol and petrolatum. Fraudulently represented as a remedy for colds and other congestions, rheumatism, neuralgia, etc—[*N J 27708, April 1938*]

Whitmarsh Blood Elixir.—Whitmarsh Laboratories, Adrian, Mich. Composition: Essentially water, alcohol (10 per cent by volume), a small amount of benzoic acid, and extracts of plant drugs including anise and an alkaloid-bearing drug. For skin poisonings (such as from ivy, oak or sumac), eczema, psoriasis, etc. Fraudulent therapeutic claims.—[*N. J. 27741; April 1938.*]

World's Wonder Massage.—World's Wonder Medicine Co., Inc., Detroit. Composition: Essentially small amounts of ammonia water, quinine, volatile oils including wintergreen and camphor, with turpentine, alcohol and water. Fraudulently represented as a cure for rheumatism, swollen feet, stiff joints, pneumonia, etc.—[*N. J. 27540; January 1938.*]

Zomogo Oil.—L. Zomogo Hood, Hot Springs, Ark. Composition: Essentially a mixture of oils, including those of petroleum, eucalyptus, mustard, clove and cinnamon. "Cure-all." Fraudulent therapeutic claims.—[*N. J. 27920; April 1938.*]

TREATMENT OF DELIRIUM TREMENS

To the Editor:—"The Treatment of Delirium Tremens," a contribution of Bowman, Wortis and Keiser in the April 1 issue of THE JOURNAL, is of especial interest to physicians who are meeting patients suffering with delirium tremens. It cannot be doubted that this complication of chronic alcoholism is one of the most difficult conditions met by physicians practicing in both general and psychopathic hospitals. The average physician or nurse is not trained in a large municipal and state institution where any considerable number of alcoholic patients are admitted for treatment. Hence many of these patients, being poorly understood, are improperly treated and the death rate therefore is inordinately high.

A study which I made some years ago revealed that the mortality from delirium tremens varied from 15 to 50 per cent in various hospitals throughout the country. The article to which reference has been made might well have referred to the fact that delirium tremens is a complication of high tolerance alcoholism and that the periodic drinker, unless he persists in maintaining a high saturation of bodily fluids over a period of many days or weeks, is not likely to have this complication. The Saturday night drinker, even though he receives some trauma to the body or head, is not likely to become delirious. The reason for this complication being confined to high tolerance drinkers is ill understood and probably is explained by the various vitamin and hepatic deficiencies described by Bowman, Wortis and Keiser. It would have been highly helpful if these writers had stressed the fact that alcoholic delirium is a condition which under the best of treatment is likely to continue from three to five days and that the surest way to raise the mortality is to endeavor to produce, by means of depressant drugs, a critical sleep from which the patient will awake with a clear mentality. It is probable that a lack of understanding of that fact accounts for the great variance in mortality rates just mentioned, since morphine, chloral and bromides in large doses, and even the barbiturates, are likely to do much harm. Physical therapy with treatment of the acidosis present and with the understanding that the patient will not do well under physical restraint and will continue to be delirious for several days should materially lower the mortality of delirium tremens. A decade and a half spent in a large municipal institution, admitting from 3,000 to 4,000 alcoholic patients annually, has still left some doubt in my mind as to whether rapid withdrawal of alcohol, because of a nonretentive stomach, a loss of ability to purchase a drink or trauma incurred on the street, which hospitalizes the patient, does not play some part in the precipitation of the delirium. During the prodromal period of delirium tremens, i. e. before hallucinosis develops, it will at least do no harm to administer alcohol. After hallucinosis is actually manifest, alcohol certainly should be interdicted.

JOSEPH C. DOANE, M.D., Philadelphia.

REGARDING A HYPOGLYCEMIC FACTOR IN THE DUODENUM

To the Editor:—The correspondence of Dr. Garfield G. Duncan on "The Clinical Application of Duodenal Extract in the Treatment of Diabetes" in THE JOURNAL, March 18, commands interest. Since Duncan and his associates (Duncan, G. G.; Shumway, N. P.; Williams, T. L., and Fetter, Ferdinand: *Am. J. M. Sc.* **189**:403 [March] 1935) administered their extract by mouth, it is not surprising that interest should attach to their therapy.

The presence of a hypoglycemic factor in crude secretin was recognized almost from the very discovery of secretin by Bayliss and Starling (Bayliss, W. M., and Starling, E. H.: *J. Physiol.* **25**:325, 1902). As early as 1906, Moore, Eadie and Abrams reported seemingly good results with the use of hydrochloric acid extracts of the duodenum and upper part of the jejunum in clinical diabetes. Since then a great deal of experimental effort has been spent in isolating this hypoglycemic factor from crude secretin.

Because boiling the duodenal extracts with dilute acids destroys the hypoglycemic effect but leaves the secretin action intact, Dixon and Wadia (Dixon, W. E., and Wadia, J. H.: *Brit. M. J.* **1**:820 [May 8-15] 1926) believe that the blood sugar reducing agent is separate from the secretory agent. This view is supported by Lalou (Lalou, S.: *J. de physiol. et de path. gén.* **14**:465, 1912), Mellanby (Mellanby, J.: *J. Physiol.* **66**:1 [Sept.] 1928) and Heller (Heller, H.: *Arch. f. exper. Path. u. Pharmakol.* **145**:343, 1929) because of the rapid destruction of secretin by pepsin and trypsin, which do not affect the hypoglycemic agent. Finally, methods were devised (La Barre, Jean, and Still, E. U.: *Am. J. Physiol.* **91**:649 [Jan.] 1930) by which crude secretin could be separated into two fractions: one possessing but little secretagogic but highly hypoglycemic action, the other actively secretagogic and not at all hypoglycemic.

The question then raised was whether the hypoglycemic agent might represent insulin extracted from the duodenum. Heller in 1929, using insulin-extracting methods on beef intestine, found no insulin in mucosa of the upper part of the small intestine. About the same time La Barre and Still, utilizing the fact that insulin is inactivated by pepsin-hydrochloric acid, failed by this method to destroy the hypoglycemic action of crude secretin. On the same basis, the effectiveness of the oral administration of duodenal extracts to lower the blood sugar in diabetic dogs reported by La Barre (*Bull. Acad. roy. de méd. de Belgique* **14**:469, 1934) and in diabetic patients by Duncan and his associates speaks against its being merely insulin. Finally, using the method of pancreatico-jugular anastomosis between adrenal-decapsulated dogs, Zunz and La Barre (Zunz, E., and La Barre, Jean: *Comp. rend. Soc. de biol.* **99**: 335 [June 29] 1928) observed a lowering of blood sugar after the intravenous injection of nonhypotensive secretin in the donor which was much less marked than that in the recipient. This, of course, would not be the expected result if the extract were insulin.

Since crude secretin contained an agent other than insulin, investigators attempted to determine whether this agent acted by stimulating the pancreas or was capable, by itself, of lowering the blood sugar. In animals there are numerous experimental results which support one or the other action, but those of Zunz and La Barre (*Bull Acad. roy. de méd. de Belgique* 8:801, 1928) appear to support a dual mechanism. Using adrenalectomized dogs with pancreaticojugular anastomoses, they found that purified secretin injected into the donor dog caused a drop in blood sugar in both the donor and the recipient, with the fall more marked in the latter. Since in this experiment the donor is physiologically depancreatized, the results given may be interpreted as a double action of the hypoglycemic agent. This concept is fortified by their results

with jugulojugular anastomoses: the injection of secretin into the donor produced only a slight decline in the recipient, and this was less marked than that which occurred in the donor.

In human subjects both in normal persons and in patients with mild diabetes, we (*Ann. Int. Med.* **11**:1563 [March] 1938) have repeatedly been able to prevent alimentary hyperglycemia following the absorption of amounts of dextrose ordinarily adequate to produce a sharp rise in blood sugar. We accomplished this by duodenal mucosal stimulation during the time of absorption of dextrose. In one instance we were fortunate in having available for study a patient with very severe diabetes who had either a diffusely calcified pancreas or intrapancreatic ducts which contained stones in many of its branches. By roentgenograms we were able to visualize many small diffusely calcified areas in the region of the pancreas. In this patient duodenal stimulation under the conditions described failed to prevent the rise in blood sugar that occurred after the absorption of a similar amount of dextrose when duodenal stimulation was omitted. These results lead us to believe that in man the hypoglycemic duodenal agent acts essentially through islet stimulation. Further, that, if true, little can be expected from the use of duodenal extracts in the treatment of diabetes in man; in mild cases of diabetes some effect may be seen from islet stimulation; in severe diabetes there will probably be no effect or even an injurious one by stimulation of already severely damaged islets.

MANAGEMENT OF TETANY

To the Editor:—The article by Margolis and Krause (THE JOURNAL, March 25, p. 1131) raises an important point that is not generally accorded sufficient recognition. Despite the frequent demonstration of the importance of phosphorus in tetany, little attention is paid to this element in the dietary management of clinical parathyroid tetany. Shelling and Goodman (THE JOURNAL, March 3, 1934, p. 669) pointed out that neglect of this factor may account for the occasional refractoriness of such patients to treatment with calcium and solution of parathyroid. There are several observations supporting the view that a relatively high phosphorus intake tends to exaggerate the metabolic defect characteristic of the hypoparathyroid state (Albright, Bauer, Claflin and Cockrill: *J. Clin. Investigation* **11**:411 [March] 1932. Robbins and Kydd, *ibid.* **14**:220 [March] 1935. Allardyce: *Am. J. Physiol.* **98**:417 [Oct.] 1931). The fact is too frequently overlooked that milk, which is usually administered in large amounts in such cases, provides an excess of phosphorus as well as calcium and may actually exert a deleterious effect in parathyroprivic tetany. Objections to the use of vitamin D in this condition have been emphasized by Shelling (*Bull. Johns Hopkins Hosp.* **50**:318 [May] 1932; THE JOURNAL, March 3, 1934, p. 669; *Am. J. Dis. Child.* **47**:61 [Jan.] 1934) and Cantarow (*Internat. Clin.* **1**:230 [March] 1936; *Endocrinology* **21**:368 [May] 1937). This matter is discussed in the report in *Endocrinology* (**24**:556 [Feb.] 1939) of a case of chronic idiopathic hypoparathyroidism which did not respond to vitamin D therapy and was effectively controlled by solution of parathyroid and a high calcium, relatively low phosphorus intake over a period of five and a half years. This regimen became ineffective on two occasions when the only change consisted in an increased intake of phosphorus (and calcium) (milk) and vitamin D and again became effective when the latter were omitted.

In the article by Margolis and Krause, no statement is made regarding the phosphorus content of the diet during the period of uncontrolled tetany (seven months). It is specified that a low phosphorus diet was given for about ten days prior to the administration of dihydrotachysterol, but apparently solution of parathyroid was not given during this period.

This comment is in no sense a criticism of the use of dihydrotachysterol in parathyroprivic tetany; there can be little question of the effectiveness of this agent in this condition. I feel, however, that the fact should be emphasized that the phosphorus content of the diet must be maintained at a relatively low level during administration of solution of parathyroid before the conclusion is reached that the latter agent is ineffective. If this is done, I believe that there will be fewer instances of apparent refractoriness to solution of parathyroid in parathyroprivic tetany.

ABRAHAM CANTAROW, M.D., Philadelphia.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

OPTIMUM AIR CONDITIONS IN HOUSES

To the Editor:—Please advise me of the present opinions of the hygiene of living room temperatures. Few families have instruments for measuring humidity and many old persons complain of chilliness unless the thermometer registers from 76 to 80 F. Is this harmful? If so, what reason can be given them why it is worse than the same temperatures in summer? At what distance from the floor should the thermometer be hung?

M.D., California.

ANSWER.—Room temperatures much above 70 F. are generally considered undesirable in cold weather because they aggravate the effects of temperature contrasts when persons pass from overheated rooms to cold outside air. Because of a reduced metabolic rate and lack of resilience of the vasomotor system many elderly persons require temperatures in the upper seventies, but an attempt should be made to reduce the comfortable temperature level by suitably insulating exposed walls and by the employment of tight fitting storm sashes when such measures are justified.

Measurements of temperature are usually made at a level 36 inches above the floor and at least 3 feet away from the exposed walls. In rooms for the aged it is preferable to record the temperature at knee-height level, 18 inches above the floor.

In warm summer weather an indoor temperature of 80 F., or even 85 F., with low humidity is comfortable and desirable, from the standpoint of health, because the human organism becomes adapted to heat and cannot stand sudden drops in temperature, especially when the body surfaces are wet with perspiration. The practice of cooling public buildings to 80 F. or less in hot weather appears to be a distinct menace to the health of susceptible persons who expose themselves to such contrasts in temperature.

LIVER EXTRACT FOR HYPERTENSION

To the Editor:—In the first edition of Beckman's "Treatment in General Practice" I find reference to a liver extract used in essential hypertension. Will you inform me of the form of liver extract used in this condition and its probable value in such a condition of some three years' standing in a woman "passing through" the menopause?

M.D., Arizona.

ANSWER.—Hypodermic administration of liver extracts in the treatment of hypertension was enthusiastically advocated some ten or twelve years ago. That a vascular relaxation and transient fall in the arterial tension occur after such injections has been thoroughly demonstrated. The hepatic extracts were said to abolish the pressor effects of guanidine on smooth muscle (Major, R. H.: *J. Kansas M. Soc.* **25**:177 [June] 1925) but the evidence that guanidine is a significant etiologic factor has never been convincing.

Since then, tissue extracts other than that of liver have been given extensive clinical and experimental trial. Active preparations of muscle, brain, spleen, myocardium and pancreas (insulin-free extract) have been studied. They are all antagonistic to the action of epinephrine. It is claimed that their vasodilator activity is not due either to histamine or to choline. The active principles appear to be closely related to adenosine or adenylic acid. Knowledge, however, concerning the active

fractions of these extracts is still incomplete and their clinical application tentative and experimental.

All these tissue extracts must be given by injection, either subcutaneously or intramuscularly. The injections must be repeated two or three times a week at least. It thus becomes increasingly difficult to retain the patient's cooperation, particularly since the great majority of hypertensive persons feel well. The clinical results have proved most disappointing.

On the meager data available it is impossible to suggest the proper therapeutic approach for the patient mentioned. Hypertensive arterial disease is a highly individualized disorder, especially regarding its provocative etiology. Thus the therapy of individual cases should depend on the etiologic factors involved.

DERMATITIS FROM RED LEAD

To the Editor:—A man was first seen by me in the fall of 1937 because of a generalized erythematous and intensely pruritic dermatitis involving the whole body more or less uniformly. He was a tall blond, middle aged Scandinavian and for eight months had been employed on a dredge. His work was painting metal on the dredge with red lead, which he did for about six months. After this time an irritative erythematous dermatitis developed in both popliteal regions and over both hip areas. He quit work immediately and consulted a physician, who treated him symptomatically without improvement. Because of the gradual spread of the dermatitis he consulted a skin specialist, who hospitalized him, and he remained in various hospitals under the care of various specialists about seven months. On the basis that this was a contact dermatitis or a cutaneous manifestation of a systemic poisoning, conservative management consisted of calamine in oil with 1 per cent phenol packs, boric acid packs, Rowe's elimination diet, numerous antipruritic ointments and sedation. This therapy was carried out in the hospitals and all orders were meticulously followed. For the next several months the patient experienced remissions and exacerbations, but in the last analysis the condition remained stationary. The elimination diet revealed nothing significant, and sodium thiosulfate intravenously was given daily and fractional doses of superficial roentgen therapy were given over the entire body, small areas at a time. Patch tests could not be done because of the extremely irritated condition of the skin. There were removed from his bed one or two cupfuls of branny, desquamated skin. His condition remained about the same, so he was sent to the university hospital for further care, only to return in about the same condition. Finally about ten months after the onset there was a gradual but definite improvement, and after a siege of about twelve months his skin again became normal. Search was then instituted for a probable offending agent in his residential and occupational environment, and by patch tests he was found definitely sensitive to some of the red lead that he had previously used. Could this have been a generalized dermatitis due to lead or lead oxide or to systemic lead poisoning? Have there been like cases reported in the literature? What further therapy could have been used? What is the value of x-rays or ultraviolet rays in the treatment of this condition? Is the use of sodium thiosulfate logical? Please enumerate references to be found in the literature about this type of dermatitis.

M.D., Minnesota.

ANSWER.—The case described brings out many factors to be considered in a diagnosis of dermatitis due to paints.

First, "red lead" or minimum (Pb_3O_4) is not often used today in red paints or, if it is, only in small quantities. Even white lead is sparingly used because of the hazard of lead poisoning.

There are many substitutes for red and white lead, and these substitutes are the ones extensively used as paint pigments. The red pigments most frequently used are made from synthetic dyestuffs, the principal red ones being paranitraniline red, No. 44 in the Colour Index, lithol red 2G, No. 166, toluidine red, No. 69, alizarin, No. 1036, and eosin, No. 771 in the Colour Index. The coal tar pigments are used in the form of lakes, which are made by precipitating organic dyes on inorganic bases, the lake thus formed being similar to a dyed fabric. Other red pigments used are mercuric sulfide, red oxide of iron, cadmium sulfide, selenium sulfide, red oxide of mercury and chrome red or basic lead chromate. A few of the natural dyes such as madder and cochineal are also occasionally used as lakes in paints. The principal bases used for lakes are precipitated barium sulfate, known as blanc fixé, barite, and sometimes white lead (basic lead carbonate) and lead sulfate. From this it is evident that the patient's actual exposure to lead may have been none at all or very little. In order to make sure of this, it would be necessary to make a chemical analysis of the paint that the patient used.

Paints, in addition to the pigment, contain a medium of drying oil and a thinner. The drying oils may be tung oil, linseed oil, castor oil, perilla oil, soybean oil, cottonseed oil, pine oil and fish oil.

The thinners are turpentine or turpentine substitutes such as petroleum distillates. In addition to this, paints also contain driers which may be organic or inorganic, such as the linoleates of metals and the oxides of metals.

The most likely substances in paints from which a contact dermatitis may be developed are the thinners. Hypersensitivity may also be present toward some of the drying oils and toward some of the pigments, especially the synthetic dye lakes.

Lead has not been reported to have caused dermatitis. It would have been interesting to examine the patient for the symptoms of lead poisoning or lead absorption such as colic, blue line on the gums, anemia, weakness of the extensors of the wrists, albuminuria and punctate basophilia ("stippling") and to examine the urine and feces for the presence of lead, especially after the administration of sodium thiosulfate.

Since dermatitis is not one of the symptoms of lead poisoning, the dermatitis was not from that cause. If it was a contact dermatitis, it would be natural to suppose that it would have started first on the parts exposed to the paint, i. e. the hands and the face. Also if the patient had a contact dermatitis from any of the ingredients in the paint he should ordinarily have recovered more rapidly than he did when exposure was eliminated, and he should not have had remissions and exacerbations while he was not working and was under treatment. So far as the patch tests are concerned, it is not stated whether a patch test was done with dry pure red lead (Pb_3O_4) or with the paint that the patient called "red lead" or whether the patch test was performed with the dry paint or the wet paint. Wet paint containing a considerable amount of turpentine or turpentine substitute will cause a positive reaction on most persons if left on the skin as a patch test for twenty-four hours; the thinner in most cases is a primary irritant. If the patch test was done with dry paint and a positive reaction was obtained, the pigments, oils and driers must be considered as possible causes of the dermatitis.

It is not believed that the case was one of dermatitis due to systemic lead poisoning, nor is it believed that it was a contact dermatitis due to lead, unless red chromate of lead was the pigment used, and then the dermatitis may have been due to the chrome radical in the compound rather than to the lead radical. Although there have been many cases of dermatitis reported in the literature as due to paint, there have been none attributed to lead poisoning.

No further treatment than that already given can be suggested.

In view of the doubtful diagnosis, no comment can be made as to the value of x-ray, ultraviolet or sodium thiosulfate therapy.

Has a diagnosis of dermatitis exfoliativa (Hebra's disease) been considered?

SO-CALLED BLACK DERMOGRAPHISM FROM GOLD JEWELRY

To the Editor:—I would appreciate information regarding the chemical reaction that causes the precipitation of a black scum whenever a gold wrist band or other jewelry, for example, a neck piece, comes in contact with skin. What can be done to prevent it?

SIDNEY F. LEBAUER, M.D., Greensboro, N. C.

ANSWER.—Endin and Kismenko discussed this phenomenon in 1925, noting that it occurred most often on dry skin smeared with fat and powder. In spite of this pertinent observation, they favored the idea that the phenomenon was another sign of hysteria. Breitman in 1928 thought it dependent on the character of the natural cutaneous lipoids. Jurjew in 1928 reported a case of adiposogenital dystrophy in which stroking the skin with a metal instrument resulted in back stripes. Soon afterward, Hauck and Dietal and Hosp (Hosp, E.: Untersuchungen über die "Schwarze Hautschrift," *Dermat. Wchnschr.* **91**:1895 [Dec. 27] 1930) reported investigations demonstrating that soft metals make more distinct marks than hard ones and that the tendency to respond with black marks is not increased by sweat (actually decreases it), fat or alkalinity or acidity of the skin or by mechanical, chemical, photochemical or thermal changes in the skin. On the other hand, they found that zinc oxide ointment made this black writing with a metal instrument possible on any skin and that the marks consist of fine particles of the metal which have been rubbed off by friction on the zinc oxide and have been quickly oxidized by contact with the air.

After an ordinary bath, enough power still adheres to the skin to produce the phenomenon; but after thorough scrubbing or cleansing with benzine the black marks cannot be produced. Parts below the powdered area, or parts in contact with clothing that has rubbed on the powdered area, are also susceptible to marking because of the transfer of powder. The skin of one who

is not susceptible can be made so by rubbing it with a cloth which has rubbed the skin of a susceptible person. After the application of zinc oxide ointment any skin will show the phenomenon. On live skin the ability to respond with black marks is only temporary, disappearing in a few hours. On the skin of a corpse it remains for a long time, until removed by rubbing or washing. Many substances besides zinc oxide will produce this condition: calcium or barium sulfate, calcium carbonate, white lead, fine salt or fine sand. Coarse powders, such as coarse sand, will not produce it, nor will the various starch powders or talcum powder.

Lead and metals softer than lead will write on clean dry skin. Silver and harder metals require the presence of a fine powder.

The phenomenon has been called black dermographism. Technically correct, it seems advisable to reserve the name dermographism for the ability possessed by some skins to respond with wheal formation to pressure or stroking.

If patients use only talcum or starch powders they will not be annoyed by black marks from the contact of jewelry with the skin. The possibility of face powder containing harder components sifting down onto the chest must not be forgotten, however.

EMPYEMA OF GALLBLADDER

To the Editor:—What are the probabilities for a postoperative hernia following cholecystostomy for empyema of the gallbladder in terms of percentage? Does chronic alcoholism have any influence? If so, what is it? Just how much of a factor is diabetes mellitus, if any, in connection with such a postoperative hernia? What is the incidence of unabsorbed sutures in connection with the operation mentioned? In case of an infected wound from the empyema would an unabsorbed suture cut any figure in the event of a postoperative hernia? M.D., California.

ANSWER.—No figures have been found on the incidence of postoperative hernia following cholecystostomy for empyema of the gallbladder. It is doubtful that chronic alcoholism or diabetes would be a factor in such a case, although infections prosper in the presence of diabetes. An unabsorbed suture would be unlikely to play a part.

The principal difficulty is the virulent infection usually present in an empyema of the gallbladder. The fascia should be sutured with interrupted chromic catgut and not too tightly and ample drainage of the gallbladder should be carried out, every effort being made to prevent infection, at least widespread infection, of the fascia. Despite these measures, postoperative hernia will inevitably occur in a small percentage of cases.

COMPLEX ALKALI VAGINAL DOUCHE

To the Editor:—I would appreciate your opinion of the following formula: sodium bicarbonate 16 ounces, sodium borate 16 ounces, sodium chloride 5 ounces, sodium benzoate 1 ounce, menthol 1 drachm, bordeaux red 8 grains, oil of thuja 1 drachm. I have been using this formula for my gynecologic patients as a general douche for the past three months. Results are satisfactory and patients seem to like it, stating that they feel clean and refreshed after douching. Some patients use it two or three times daily. I should like to know whether prolonged use of this formula can cause any temporary or permanent local or systemic damage. Are the drugs in the formula used in proper proportion? If not please recommend the proper concentrations. In addition, please suggest whether the efficiency of the formula can be improved by omitting or adding different drugs. M.D., New Jersey.

ANSWER.—There is no need for such a complicated douche, particularly because it is no better than most simpler and cheaper douches. In fact this douche may in some cases do harm. Practically all the ingredients in this douche have an alkaline reaction and, as Roblee and Karnaky have shown, alkaline douches may have a bad effect on the cervix and the vagina. In fact Roblee maintains that an alkaline medium in the vagina may result in the formation of "erosions" on the cervix. A simple way to cure such erosions is to maintain an acid medium in the vagina.

Nearly all pathogenic organisms in the vagina, especially the gonococcus and the trichomonas, disappear if the vagina is kept strongly acid. In gonorrheal vulvovaginitis in children, for example, cures can be obtained in nearly all cases by using acid tablets in the vagina. In the cases of vulvovaginitis in which estrogenic substance is used, cures are obtained only in the cases in which the vaginal reaction is acid.

From the foregoing remarks one may conclude that alkaline douches are not only useless except as mechanical cleansers but may actually do harm. Only acid douches should be used. The best substances for douching are lactic acid and vinegar (5 per cent acetic acid). Vinegar is cheaper and somewhat better. If lactic acid is used, one teaspoonful of it should be added to two quarts of warm water. When vinegar is used, four tablespoonfuls should be added to two quarts of warm water.

SULFANILAMIDE AND CONVULSIONS

To the Editor:—A boy aged 19 months and weighing 30 pounds (13.6 Kg.) was given an initial dose of 20 grains (1.3 Gm.) of sulfanilamide (orally) for acute follicular tonsillitis. This condition was present for two days before the administration of the drug, and the temperature varied from 100 to 105.8 F. With the high temperature the child was delirious. On the third day of illness there was no fever. A consultant pediatrician found the tonsils enlarged and reddened. He advised that sulfanilamide be given in the quantity stated. About twenty to thirty minutes after this was done the child uttered a peculiar cry and turned blue, and his extremities became rigid. He immediately became agitated and kept on throwing himself around on a couch. There was no loss of sphincteric control and no biting of the tongue, although the child did grind his teeth and almost presented risus sardonicus. At times he would assume the position of opisthotonos and right after that would throw himself around on the couch. He was given one-eighth grain (0.008 Gm.) of morphine sulfate by hypodermic injection. This helped after about twenty minutes. He was then taken to a hospital, where a spinal tap was performed, because it was thought that cerebrospinal meningitis should be ruled out. The cerebrospinal fluid was under increased pressure, sugar was present, globulin was not increased and there were 6 lymphocytes present. No further tests were done on this fluid. Examination of some catheterized urine was negative. A blood count showed the hemoglobin and red cells to be normal. There were 4,400 white cells, and the differential showed 61 per cent polymorphonuclears, 39 per cent lymphocytes and a shift to the left. The temperature on admission to the hospital was 101 F. The convulsive movements lasted about two hours. After this spinal tap a second pediatrician was called in. At this time the child was asleep or, rather, comatose. The reflexes were all diminished but present. The consultant believed that the convulsions might have been due to the tonsillitis but did mention the possibility of an influenzal meningitis with good prognosis. He also stated that there was a good possibility of this being a case of acute encephalitis. I might add that during the convulsive state the child's eyes would roll backward toward his head and his tongue would be pushed out of his mouth and even deviated to either side. A third pediatrician was then called in and he stated that the convulsions were due to the sulfanilamide. The father of the child suffers from hay fever and bronchial asthma. This consultant admitted never having seen any convulsions due to the administration of the drug. He explained that there was most likely a condition of acidosis present which was brought on by the sulfanilamide. The urine, however, was distinctly alkaline. The infant was given 30 grains (2 Gm.) of sodium bromide rectally and 1/250 grain (0.0003 Gm.) of atropine sulfate. During the night he was restless and cried often, and his hands would assume athetoid positions while the rest of his extremities were at times rigid. The next day he was a little improved and no longer comatose. He sat up in his crib, asked for water and drank it alone. He had a peculiar facial expression which was dull and vacant. He seemed to be puzzled by everything around him and his eyes had a far away look. It seemed as if he was not in contact with reality. Then again he would become quite normal for a minute or two, speaking distinctly and quite lucidly. During the day while he was no longer comatose the child would still keep on posturing with his hands but to a lesser degree than he had the night before. Forty-eight hours after admission a second tap was performed and now the cerebrospinal fluid was not under increased pressure. There were only 2 cells, sugar was present and the amount of globulin was normal. The fluid was crystal clear in each tap and only about 5 cc. was removed each time. The third day of hospitalization he was still improving mentally and a second blood count showed it to be entirely normal. Sixty hours after the onset of the convulsions a maculopapular eruption developed behind the ears and on the scalp line. It was also present on the thorax. There was no fever and the cutaneous lesions did not appear pruritic. During the day the rash would become quite faint and then reappear. It lasted about twenty-four hours. The tonsils were improved. All told, the child remained in the hospital about four and one-half days and made a complete recovery. The mother states that a similar rash developed at home a few days after this but I was not called to see it. Do you think that the sulfanilamide was the cause of the convulsions? What facts in the history as presented would make you agree or disagree with this as the cause? What is the most likely explanation of the rash? Do you know of any cases in which sulfanilamide per se caused convulsions in human beings?

M.D., New York.

ANSWER.—It does not seem probable that the convulsions were caused by the sulfanilamide in view of the fact that the dosage was small. It would seem more likely that the relationship between the convulsions and the ingestion of sulfanilamide was coincidental, in view of the fact that such a relationship has not been reported despite the widespread use of the drug in recent years, and that the convulsions were associated with the infection in view of the not infrequent occurrence of convulsions with acute infectious diseases in childhood. Furthermore, the eruption can be explained as an accompaniment of the infection, also in view of their frequent occurrence in various febrile states.

The toxic manifestations from the use of sulfanilamide have in most instances resulted from fairly large doses. Among such are dizziness, headaches and mental confusion. The maculopapular eruptions have been noted particularly after exposure to light and it has been suggested that the cutaneous reaction is due to a vasculotoxic effect of porphyrin; some observers have reported abnormally high values in the urine of patients taking sulfanilamide. In the present case no determination was made of the amount of sulfanilamide in the blood, but it must have been at a low level and could probably not account for any of the toxic symptoms that have been associated with the taking

of sulfanilamide. Such laboratory data as the carbon dioxide combining power of the blood, the oxygen saturation and the amount of sulfanilamide would be necessary in order to say whether or not the convulsions were due to an associated acidosis and whether or not the cyanosis was due to the sulfanilamide. So far as is known, there are no reports of convulsions in human beings caused by sulfanilamide.

INCIDENCE OF TRICHINOSIS

To the Editor:—In the January 26 issue of the *Fränkische Tageszeitung* in Germany, I find the amazing statement that 17 millions of Americans are suffering from trichinosis, with a mortality of several thousand in the past year. This was declared by Dr. Nelson, a professor at Rutgers University—according to the German paper—in an address delivered to the health department of New York City. He is also quoted as having said that trichinosis in the United States is one of the most prevalent diseases and that no meat inspection is made in more than 30 per cent of the samples submitted for examination. He is further quoted as having closed his speech with the sentence: "Nothing is done to protect the people, but, nevertheless, they build skyscrapers." In view of the tendency of the German press to spread false news about conditions in the United States, I would appreciate an informative reply to my inquiry. Is there a reliable statistical estimation as to the prevalence of trichinosis?

LEO F. BLEYER, M.D., Elmira, N. Y.

ANSWER.—The information from the German press cited was based on an address given by Thurlow C. Nelson, Ph.D., professor of zoology, Rutgers University, New Brunswick, N. J. The title of the paper given by Professor Nelson was "The Trichina: Public Enemy Number One Among Parasites of the Metropolitan Area." It was presented before a conference of health officers of the New York metropolitan area January 24.

The statement that 17 millions of Americans are suffering from trichinosis was based on extensive postmortem studies that have been carried out in recent years. Because of more refined methods, a large proportion of postmortem material now reveals the presence of Trichinella. Most investigators have used the method of digesting the diaphragms removed at necropsy in artificial gastric juice and of then examining the sediment for larvae. Others have combined with this procedure a microscopic examination of the muscle. The incidence of the disease in terms of percentage of necropsy material containing larvae in various parts of the country is as follows: Rochester, N. Y., 17.15 per cent; Boston, 27.6 per cent; Minneapolis, 17.09 per cent; New Orleans, 3.5 per cent; San Francisco, 24 per cent; Washington, D. C., and Baltimore, 13.67 per cent; Chicago, 14 per cent; St. Louis, 15.37 per cent. A more refined technic used in Cleveland brought the incidence up to 36 per cent. It should be pointed out that in practically all the material examined death was ascribed to some other cause. It is difficult to determine the death rate of trichinosis. If it is based on cases recognized during life, the rate is low. On the basis of the foregoing postmortem observations, it is obvious that many cases of trichinosis are not recognized or properly diagnosed. It is well known to most clinicians that the disease may be easily confused with many other conditions. Furthermore, not all cases present the classic laboratory evidence of eosinophilia. An advance in the diagnosis of trichinosis has been made recently through the utilization of cutaneous and serologic tests. While a study of postmortem material will not give an accurate estimate of the incidence of trichinosis in the population at present, it nevertheless indicates a definite trend and that the disease is much more common than the experience of the average physician would indicate.

The late Dr. M. C. Hall, chief of the division of zoology of the National Institute of Health in Washington, D. C., stated in 1938 that the federal government inspects only about 70 per cent of the meat in this country. It is recognized that the remainder is inadequately inspected. The federal government inspects only the meat of packers who engage in interstate commerce. Even the federal inspection is inadequate, since no practicable provision is made for pork sold which is intended to be cooked; inadequately cooked pork appears to be the source of most cases of trichinosis.

It is of interest that toward the end of the last century Germany prohibited the importation of pork produced in America, because it was the belief that the high incidence of trichinosis in Germany was due to infected meat imported from the United States. The Germans contended that German meat sold in Germany was free from Trichinella because of an elaborate system of microscopic inspection of all pork for larvae. This examination would prevent the sale of trichinous meat; therefore the source of human cases of trichinosis must be due to imported American pork products. The United States instructed Dr. C. W. Stiles in 1898 to determine the value of the German system of pork inspection. His conclusions, after two years' observation, showed that out of 6,329 cases of trichinosis occurring in Germany between 1881 and 1898, 3,388 cases with 132 deaths appeared to have been due to faults of the method of German inspection. There are no reliable statistics on the incidence of trichinosis in Germany at present.

There is no doubt that trichinosis constitutes one of the major public health problems of today. The United States Public Health Service has recognized this, and a number of excellent surveys and recommendations for the control of the disease have been published in the last two years. For further information concerning this subject, the following publications of the United States Public Health Service are recommended:

Hall, M. C., and Collins, B. J.: Studies on Trichinosis: I. The Incidence of Trichinosis as Indicated by Postmortem Examination of 300 Diaphragms, *Pub. Health Rep.* **52**: 468 (April 16) 1937.

Hall, M. C.: III. The Complex Clinical Picture of Trichinosis and the Diagnosis of the Disease, *ibid.* **52**:539 (April 30) 1937.

Hall, M. C.: VII. The Past and Present Status of Trichinosis in the United States, and the Indicated Control Measures, *ibid.* **53**: 1472 (Aug. 19) 1938.

Hall, M. C.: The Role of the Garbage-Fed Hog in the Production of Human Trichinosis, *ibid.* **52**: 873 (July 2) 1937.

TOE NAILS

To the Editor:—A girl aged 17, active, well nourished, healthy, vigorous and athletic, now in her third year at high school, bruised her right big toe in a basketball contest three weeks previous to my seeing her. Some two or three weeks following this the nail in this toe has become lifeless looking in appearance—a light grayish nail in good position, not distorted in growth (of dark egg shell appearance), which can be cut from above down or probed without pain. The tissue surrounding both toes is healthy and normal in appearance. There is no apparent inflammation or pus. The big toe on the other foot is likewise involved. The egg shell nail, which is associated with hyperhidrosis, has been thought of and certain debilitating diseases, but the patient evidences no such history. All the other toes are perfectly normal in appearance and growth.

M.D., New York.

ANSWER.—The egg shell nail, described first by J. N. Hyde (The Egg Shell Nail, *J. Cutan. Dis.* **24**:145, 1906) is a thin nail, white with a purplish tinge, uptilted at the free border. It is part of the picture of erythrocyanosis of the extremities associated with hyperhidrosis, the whole dependent, in all probability, on some disturbance of the endocrine glands. It is seen most frequently in young girls.

The case under discussion lacks all these criteria except change of color. Injury is untenable as a cause, for there has been no evidence of subungual hemorrhage and the symmetry of the change of color requires the assumption of an unlikely coincidence of injury also to the other big toe.

Primary discoloration of the nails is rare, resulting, according to Heller, the leading authority on diseases of the nails (*Handb. d. Haut- u. Geschlechtskrankh.*, Berlin, Julius Springer **13**:131 [part 2] 1927), from icterus, hemorrhages due to general causes, racial pigmentary peculiarities, pigmented nevi, psoriasis or endocrine disorders. Only the last two can be considered in the present case.

Addison's disease and hyperthyroidism cause change of color of the nails and it is possible that slighter endocrine disturbances may be found sufficient. Rarely psoriasis makes its initial appearance as a discoloration of the nails with thickening, followed by the thimble-like pitting, cross furrows, irregular depressions or partial separation of the nails at the free border or the sides seen so often in psoriasis. None of these changes in the nail are diagnostic, however, and only after the appearance of ordinary cutaneous lesions can the diagnosis be settled.

Loss of translucence of the nails can be secondary to anemia, particularly chlorosis, angiospasms, polycythemia, icterus and pigmentary diseases, all of which can be ruled out easily in the present case. Thickening of the nail plate or increase of the subungual horny layer may destroy the translucence. A growth of monilia or other fungus could produce the same result. Here again the difficulty is in explaining how the two big toes and no others became infected simultaneously. Scrapings from under the free border of the nail, examined in solution of potassium hydroxide, or cultures on Sabouraud's maltose agar, are indicated.

If a dressing of mercury solution was applied to the toe after the injury, the change of color of that nail can be explained; this leaves the same difficulty of explaining the corresponding alteration in the nail on the left big toe. Such a discoloration has been discussed by J. L. Callaway (Transient Discoloration of the Nails Due to Mercury Bichloride, *Arch. Dermat. & Syph.* **36**:62 [July] 1937). It is seen frequently after treatment of infections about the nails with mercury solutions or white precipitate ointment and is due to an impregnation of the nail with mercuric sulfate, which seems to be precipitated by light.

Slight changes in the nails seldom furnish much help in diagnosis. They must be considered in the light of other signs and symptoms.

POSSIBLE EPILEPTIC EQUIVALENT

To the Editor:—A white unmarried woman aged about 26, whose general physical examination is negative except for a rather low systolic blood pressure and chronic deafness, complains of "spells" which have been present for the past ten years and are gradually growing more severe, especially during the past few months. The "spells" consist of a clouding of consciousness, at which times she is unable to concentrate mentally and is not aware of what she is doing. In general they are much like conditions found in diabetic patients with hypoglycemia, the chief difference being that the spells are of short duration (from a few minutes to a half hour) and end spontaneously without treatment. She has never had a complete loss of consciousness, anything resembling a convulsive seizure, and the spells are not followed by headache or other symptoms. There has been no epilepsy or other nervous disorders in the patient's family. The following blood sugar tests have been made: Nov. 2, 1938, 87 mg. of sugar per hundred cubic centimeters of whole blood, shortly after an attack; November 14, 83 mg. also shortly following an attack; November 16, 97 mg. taken before breakfast while she was on her usual diet and on a day when she did not have a spell. She was hospitalized December 16, at which time the fasting blood sugar was 75.5 mg. One hour after her usual breakfast it was 66.3 mg. Two hours after breakfast it was 106.4 mg. One hour after her noon meal it was 97.6. Two hours after her noon meal it was 97.0. Three hours after it was 96.1. She was then placed on a low carbohydrate diet and the following morning one hour after breakfast the blood sugar was 115 mg. One hour after the noon meal it was 129 mg. The following morning she was given 90 Gm. of dextrose, with considerable water before breakfast. One-half hour later the blood sugar was 70.2 mg., one hour later 65.6 mg. and one and one-half hours later 69.4 mg. That day she had her regular noon meal and about three hours later had one of her "spells." The blood sugar test taken just as she was recovering from it showed 96.6 mg. Because she is alone most of the time it has been impossible to obtain a blood specimen at the beginning of or during an attack. The attacks are becoming more and more frequent and interfere with her work. This brings up the question as to what would be the most advisable course to follow in her case. I notice in the recent literature that some small doses of insulin frequently are a great deal of help in simple chronic hypoglycemia. I am wondering, however, if in this case the trouble might be associated with a tumor of the islands of Langerhans and if an exploratory laparotomy might be advisable. There was no sugar in the urine following the 90 Gm. of dextrose by mouth.

M.D., Wisconsin.

ANSWER.—The patient has been well studied as regards blood sugar and sugar tolerance but these laboratory data all seem to indicate that there is no remarkable disturbance in this sphere. It is unusual to see convulsive seizures due to hypoglycemia unless the blood sugar level falls below 40 or 50 mg. per hundred cubic centimeters. The attacks described might well be epileptic equivalents with clouding of consciousness. It might be helpful to test the patient for carotid sinus hypersensitivity. If this proves to be normal, studies of the cerebrospinal fluid should be made with measurement of the cerebrospinal fluid pressure. In addition roentgenograms of the skull would be helpful and finally electro-encephalographic or air encephalographic studies might be done. All these tests would help rule out some intracranial causes of epileptic seizures. It would not seem advisable to recommend exploratory laparotomy in view of the available blood sugar studies, which do not definitely indicate that there is hyperinsulinism present. A simple therapeutic test would be the administration of large amounts of dextrose daily. Also sedative medication with from 0.016 to 0.03 Gm. (one-fourth to one-half grain) of phenobarbital twice or three times a day should be tried alone or together with small doses of ephedrine sulfate 0.024 Gm. (three-eighths grain) twice a day.

PETIT MAL, PYKNOLEPSY OR FRÖHLICH SYNDROME

To the Editor:—A boy aged 14, in the fifth grade, has been having attacks which apparently are petit mal. He is rather obese, being about 6 inches shorter than is normal at his age. His external genitalia are those of a 6 year old. Evidently this is a case of pyknolepsy. What is the differential diagnosis? What further studies would you suggest? What treatment would you advise? I am planning to make a sugar tolerance test and have x-ray studies done of the head, thinking of course that there might be some disturbance of the pituitary gland. Is any type of glandular therapy indicated?

M.D., Connecticut.

ANSWER.—If this patient has petit mal epilepsy, it is doubtful that there is any relationship between the petit mal and the glandular deficiency. The brief description of the physical characteristics suggests a possible Fröhlich's syndrome. However, one would need much more information to make a diagnosis. If the condition proves to be a pituitary gland deficiency, treatment might be attempted with one of the new preparations obtained from the anterior lobe of the pituitary gland. However, before beginning treatment it is advisable to explain to the parents that the treatment is a long and fairly expensive procedure which will require two or three injections a week for six months or a year before results may be obtained. It is possible even then that there will be no results from treatment. If there are, these results will be revealed in a change in the physical characteristics of the child.

Pyknolepsy, as described by Stahrgardt, is a form of epilepsy characterized by petit mal seizures which begin some time between 8 and 10 years of age and disappear spontaneously at puberty. This condition is not affected by any treatment whatever. The diagnosis is confirmed only when the seizures stop at puberty. There are only two forms of treatment which affect the petit mal of idiopathic epilepsy. Those treatments are fasting and the ketogenic diet. Petit mal epilepsy does not respond to any drug treatment.

It would be advisable to take roentgenograms of the wrists and compare the bone age or development with the Todd standards. This will give information as to the state of metabolism of the child. Apparently there is need for an anterior pituitary male sex hormone. A dextrose tolerance test will show an increased tolerance in pituitary deficiency. More complete information would allow a more intelligent diagnosis and schedule of treatment.

"FEBRILE ANTIGENS" FOR DIAGNOSIS

To the Editor:—Lately my associates and I have been using a product of the Lederle Laboratories, New York, for our Widal tests, known as the Typhoid Group Antigens. A number of physicians on our staff have questioned the reliability of the test and I would appreciate any information that you would send me concerning this product.

M.D., Pennsylvania.

ANSWER.—The preparations formerly called "Typhoid Group Antigens," now called "Febrile Antigens, Lederle," consist of suspensions of members of the typhoid (O and H elements) paratyphoid A and B group, for the performance of the agglutination test for infections of the ordinary enteric types to be utilized in a slide test. They should give results approximately equivalent to those obtained by other methods, probably somewhat less accurate so far as concerns exact titrations.

The "Febrile Antigens" package now also contains Proteus antigen for the test for typhus fever and other members of the typhus group and Brucella antigen for the test for undulant fever (brucellosis).

Of course all such tests must be interpreted in the light of other factors and must not be depended on, of themselves, to establish a diagnosis.

SOAPS FOR WASHING DIAPERS—MEASLES WITHOUT EXANTHEM

To the Editor:—1. Will you give me a list of some of the more popular soaps which, if used to wash diapers, are not so strong as to cause a diaper rash in most babies, and also a list of the soaps which may cause irritation when so used? 2. Can a diagnosis of measles be made without the appearance of a rash? I recently saw a 17 months old baby who had been feverish and irritable and vomited repeatedly for twenty-four hours. The buccal membranes were full of Koplik spots, and, since his sister had broken out with the measles only two days previously, I thought he was also getting the measles. However, he became afebrile and was well in two days, and no rash appeared. Could it have been atypical measles?

M.D., California.

ANSWER.—1. If the diapers are properly washed, no soap should remain in them to irritate the baby's skin and cause a diaper rash, no matter what soap is used. The diapers should be washed first in soapy water, rinsed thoroughly in clean warm water, boiled in clear water for ten minutes and then again rinsed thoroughly in clean warm water. To differentiate between nonirritating and irritating soaps, any soap that can be used to bathe the baby without irritating the skin could certainly be used to wash diapers.

2. If the physician is certain that the buccal membranes were full of Koplik spots, the case undoubtedly was one of measles. Especially during epidemics, attenuated or atypical cases of measles occur in which the rash is so slight and transient that it may be undetected at the particular time of the examination.

TREATMENT OF PARKINSON'S DISEASE

To the Editor:—Please describe the latest treatment for Parkinson's disease.

S. H. RAYMOND, M.D., Cazenovia, N. Y.

ANSWER.—There have been no noteworthy recent advances in the treatment of Parkinson's disease. The most valuable agents seem to be those of the atropine group. Treatment with scopolamine seems to be as efficient as anything that has been used. Good results have been reported both with the tincture of stramonium and with a well assayed product of Datura leaves. It has also been found that atropine sulfate itself, given in increasing doses of from 1/250 to 1/50 grain (0.25 to 1.3 mg.) three times a day, has had a beneficial influence, especially in the encephalitic forms. More recently cobra venom has been used (Gayle, R. F., Jr., and Williams, J. N.: *South. M. J.* **31**:188 [Feb.] 1938).

DIGITALIS IN HEART FAILURE

To the Editor:—The use of one of the most used drugs, digitalis, at times puzzles me greatly. 1. Some lecturers in postgraduate institutions say that digitalis should be used to its full therapeutic effect at the first signs of heart failure, i. e., shortness of breath on exertion with or without cardiac irregularity, and with or without demonstrable edema either pulmonary or swelling of the ankles. In cases such as this, if the examiner feels definitely that the shortness of breath is cardiac, should digitalis be used to its full therapeutic effect? 2. Cases such as the following are not infrequently seen. An individual in middle life has had a coronary thrombosis or some other acute cardiac episode. Within several months there is gain in weight, shortness of breath, pulmonary edema, a heart rate from 90 to 100 usually regular, and there may or may not be enlargement of the heart. The use of aminophylline and mercurial diuretics is necessary. A particular case I have in mind is a person who with the use of mercurial diuretics puts out between 136 and 172 ounces of urine following each injection. Should digitalis be used in its full therapeutic effect in a case such as this?

M.D., New York.

ANSWER.—1. Digitalis should be administered to get full therapeutic dosage, slowly or rapidly as the need indicates, at the first sign of heart failure, whether the evidence is pulmonary or systemic. It sometimes can be used as a therapeutic diagnostic test.

2. With respect to the example cited of the middle-aged patient with left ventricular failure and normal rhythm, digitalis is just as much indicated as in any other case of heart failure. It may not be quite so effective as when there is auricular fibrillation, but nevertheless it should be used in full, even before diuretics. It may often, together with rest, be so effective that diuretics are not needed.

TREATMENT OF PAINFUL VACCINATION SCAR

To the Editor:—A white girl aged 16 years consulted me about a smallpox vaccination scar, one year old. The scar is one-half inch in diameter and raised one-eighth inch above the surrounding skin. She plays basketball and when the scar is bumped it becomes painfully itchy. Would there likely be a return of scar tissue if this scar was excised about one-eighth inch beyond its borders? What would be the simplest and best treatment? Would quick, brief freezing with "dry ice" be feasible?

M.D., Washington.

ANSWER.—The simplest and best treatment of this old vaccination scar would be a delicate excision with a minimum of trauma and close coaptation of the skin edges with a subcuticular stitch and follow up with roentgen therapy to the incision to prevent the recurrence of keloid. "Quick, brief freezing with dry ice" is not a satisfactory procedure in the treatment of old thick keloids. In view of the fact that the scar is painful and itchy at times it would be well to examine it microscopically, after excision, to rule out the existence of a cutaneous neuroma.

ARTIFICIAL APPENDAGE FOR LOSS OF FINGERS

To the Editor:—A right handed farmer, aged 50, has lost the digits, save the thumb, of the right hand. The line of cleavage is diagonally from the first metacarpophalangeal joint across to the middle of the fifth metacarpal. What type of artificial appendage would be the most useful to this man in his work? Appearance is decidedly secondary.

BENJAMIN CARLSON, M.D., Lorain, Ohio.

ANSWER.—The most useful type of artificial aid to function would consist essentially of a prosthesis of firm leather which could be strapped or laced to the hand and wrist and to which is attached a broad, semiflexed metal finger, in the position of the middle and ring fingers, to the tip of which the patient could firmly approximate the thumb.

A simple apparatus is far more likely to prove useful than a complicated one; and what this patient needs most is something that will permit him to grasp objects with the help of the prosthesis and the remaining thumb.

ACID-ASH DIET

To the Editor:—A question with regard to the "acid-ash diet": Why is salt contraindicated? Send me, or refer me to, an acceptable acid-ash diet list.

M.D., Texas.

ANSWER.—Diets providing an acid ash are sometimes used in the dietary treatment of renal diseases, particularly when the condition is associated with edema. As a rule, dietary treatment is not sufficient but is supplemented by the administration of acidifying salts such as ammonium chloride. Foods which provide an acid ash are cereals, including bread and other cereal products, meats, eggs and fish.

Discussions of acid-ash diets with information about foods can be obtained from almost any standard textbook on nutrition. Salt is contraindicated. It may be easily retained and thus lead to an accumulation of edema fluid, for the elemination of which the acid-ash diet usually is given. It is customary to substitute salt-free butter for ordinary butter and otherwise to avoid excessive ingestion of table salt.

SPONTANEOUS RUPTURE OF MEMBRANES NEAR TERM

To the Editor:—If the membranes rupture, allowing the amniotic fluid to escape during the last month of pregnancy, is it always advisable to induce labor promptly?

M.D., California.

ANSWER.—Labor should usually be induced in patients in whom the membranes rupture near term. A latent interval usually follows the rupture of the membranes until contractions commence. It is therefore best to wait as long as twelve hours before an induction is undertaken, if indicated, in order to allow a possible spontaneous onset of labor to take place and to assure the best response to the induction. It may be difficult to determine definitely that the membranes have actually ruptured. If this is questionable, nothing should be done. The danger of prolonged rupture of the membranes is infection. Although intra-uterine infection occurs but rarely in such cases, it is always a serious complication.

FIBRIN IN AMNIOTIC CAVITY

To the Editor:—During 1937 I delivered a 21 year old primipara by low forceps and episiotomy and she had a normal puerperium. In May 1938 she returned with amenorrhea, vaginal pruritus and an enlarged uterine fundus. June 4 she had severe abdominal cramps and profuse vaginal bleeding with clots, which continued off and on for two and one-half weeks. A miscarriage was agreed on but no tissue was passed. June 28, reexamination revealed a white flaky discharge and she was started on silver picrate insufflation and suppositories and two weeks later the fundus was still enlarging. She continued a normal pregnancy and delivered a normal male infant November 22, weighing 6 pounds 5 ounces (2,863 Gm.). There were no lacerations and the membranes were ruptured just before the delivery of the head with the escape of a moderate amount of crystal clear water. The placenta was delivered after the baby and was inverted as it presented with two thirds of the inner surface of the membranes covered with a layer of fibrin from one-eighth to one-fourth inch in thickness. There was no laceration of the placenta, cord or baby. The maternal surface of the placenta was apparently normal. My impression is that there was bleeding into the amniotic cavity in June, which resulted in the deposit of fibrin. Is this a frequent occurrence?

M.D., Kentucky.

ANSWER.—It is difficult to explain a deposit of fibrin within the amniotic cavity. This would have to result from bleeding from the cord or the fetus. Fibrin deposits such as the one described are often found extra-amniotically, so that the amnion in this area is considerably thickened. These represent hemorrhage and organization of the blood clots. The hemorrhage may occur early in pregnancy in association with a threatened abortion or late in pregnancy as the result of changes incident to placenta praevia. Microscopic examination of such an area will reveal the organized blood clot.

CONTRALATERAL PHLEBITIS YEARS AFTER INJURY

To the Editor:—A patient was shot with shrapnel in the right leg during the World War and has since suffered with atrophy and severe pain in this member. Since he is forced to favor his right leg in walking or working, a phlebitis has developed in his left leg. In 1916, about two years before his entry into the service, he suffered an attack of typhoid. The phlebitis that now exists in the left leg began only five or six years ago. Now the question is whether or not the phlebitis was produced by the attack of typhoid over fifteen years previous to its onset or could be caused by the gunshot wound in the right leg, which has forced him to use the injured leg a great deal more than he would normally. I have talked this matter over with the rating board of the Veterans Administration and was informed that this particular combination had never been submitted before. If possible I wish that you would let me know if it is possible for a gunshot wound which produced a compound fracture in the right leg to cause a phlebitis in the opposite leg.

STANLEY M. GATES, M.D., Monticello, Ark.

ANSWER.—More data are necessary to form an opinion. One would have to know whether there were any clinical symptoms and signs of venous obstruction during or immediately after the attack of typhoid. It is not likely that the patient had a residual phlebitis on entering military service, as this would have disqualified the patient for service at the front. Another question that arises is whether or not a phlebitis followed the leg injury within a few weeks. In the absence of such evidence, a phlebitis occurring sixteen years after typhoid or fourteen years after a gunshot wound, without any "bridging symptoms," cannot be admitted as having any causal relationship either to the infection or to the injury.

The term "bridging symptoms" is meant to indicate that a phlebitis can be due and can appear in the form of recurrences

as long as twenty-five years after an injury, but the initial attack must be demonstrable and also the recurrences at intervals. The idea that favoring the right leg can bring about a phlebitis in the left leg, again, cannot be substantiated, unless there is good evidence that a femoral or pelvic phlebitis existed at the time of the injury. Otherwise every major amputation would be followed by phlebitis in the other limb, and this certainly is not the case.

In deciding on the merits of such a case, much would depend on the ability to demonstrate the existence of a phlebitis within a few weeks after the infection or injury.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, April 22, page 1627.

Book Notices

Spinal Anesthesia. By Louis H. Maxson, A.B., M.D., Practicing Specialist in Anesthetics. Foreword by W. Wayne Babcock, M.D., LL.D., F.A.C.S., Professor of Surgery, Temple University School of Medicine, Philadelphia. Cloth. Price, $6.50. Pp. 409, with 70 illustrations. Philadelphia, New York, Montreal & London: J. B. Lippincott Company, 1938.

"The writer, being large, middle aged and bald, can hardly qualify as an 'auburn-haired vamp,' but he feels that the spinal anesthetic patient should preferably be watched by a well trained medical man who is qualified personally to administer any treatment or restorative measures that may be called for." One has the impression on reading Dr. Maxson's book that he is indeed reading the words of a well trained medical man who is qualified and who, moreover, has his feet on the ground in a controversy that has waxed warm during the past ten years. The book is definitely on the side of spinal anesthesia. The protagonist is an anesthetist but the book is not controversial. Dr. Maxson goes out of his way to meet all comers but not for the purpose of blasting them into an admission of their errors. He introduces the reader to them in their own words and if he disagrees with them he says so; yet the background of his reasoning has been so painstakingly set forth that the reader understands why he disagrees and is likely to concur. He has correlated the results of present and past clinical and experimental work intelligently, accurately and impartially, thus fulfilling a long felt need. It is this painstaking and thoughtful consideration of the known facts regarding the basis of spinal anesthesia that makes the book worth reading and keeping as a reference work.

Following a foreword by Dr. W. Wayne Babcock, "to whom spinal anesthesia in this country owes a great debt of gratitude," there is a sane preface by the author, in which it is stated that "the entire purpose of this presentation of the subject is to help the reader understand the 'why' of each procedure, and with such understanding to enable him to evolve a technic of his own, properly grounded on scientific principles." This he proceeds to do successfully. The book is not a compilation of the author's cases. First there are an explanation of the definitions and synonyms used and a brief and accurate history of the method. A chapter of careful and practical discussion of anatomic considerations follows. There is in this chapter a detailed account of the spinal and autonomic nervous systems which is of paramount importance and is referred to again and again in the text because the bulk of clinical and experimental evidence adduced indicates that fall in blood pressure, respiratory embarrassment or failure and cardiac insufficiency are truly the effects of the anesthetic drug on cord structures and their autonomic counterparts. The selectivity of most anesthetic agents is on sensory components predominantly in the concentrations ordinarily used. Most of the untoward events therefore are the results of gravitation of the anesthetic to nerve roots controlling the muscles of respiration, the sympathetic acceleration of the heart and the peripheral nervous vasomotor control. The physical factors in the administration of spinal anesthetics are reviewed, as are the actions of drugs that have been or are being employed as anesthetic agents for premedication and stimulation during anesthesia. A discussion of technical considerations is followed by the recording of specimen technics. These include all the well known methods. The author has no particular ax to grind and does not give the impression that he has any interest in wanting to persuade the reader to adopt his technic (which in fact is similar to that used by many other operators).

The effects of anesthesia are dealt with, and here the earlier experimental and clinical groundwork is repeatedly referred to in the explanation of the phenomena observed during and after anesthesia. The cause of failures is (again) shown to be failure to deposit the anesthetic in the subarachnoid space in the vast majority of cases, although hyposensitivity to ordinary concentrations is thought to be a rare cause. Difficulties of administration and dangers to be watched for are described and the causes of death analyzed. Maxson is certain that, when handled by a well qualified anesthetist, spinal anesthesia is "as safe as any method can be." One believes him when he states that it would be his own choice had he to undergo an abdominal operation.

There is obvious sincerity about the book, and one gathers that the same might be said about the author. He records his own deaths in detail and gives all the mortality statistics which have been reported since 1915, making the point that most deaths have occurred early in the given series. Complications and sequelae, advantages and disadvantages, indications and contraindications are thoroughly considered, so that one may find almost any specific condition discussed from the standpoint of risk. The author considers spinal anesthesia to be of value at times as an aid in diagnosis (although not all surgeons will be willing to agree that it should be used to differentiate mechanical from paralytic ileus), as a therapeutic agent in certain conditions and as an anesthetic agent in some special situations, such as childbirth. The application of the method in the surgical treatment of children and infants is discussed, the author's point of view being that it may have a use with older children but probably not under any ordinary circumstances with infants. In the same chapter preoperative and postoperative care of patients who have had a spinal anesthetic is presented. Total spinal anesthesia is discussed, chiefly for the purpose of warning against its dangers and by way of illustrating the selectivity of the drugs used for sensory nerves. Segmental spinal anesthesia is thought to have promising possibilities. The book closes with a brief chapter of conclusions, the first part of which might fittingly have introduced the treatise. In it the spirit in which the book was written is indicated by the statement that "the writer of this book is not an extremist in his attitude toward spinal anesthesia. He cannot share the high enthusiasm of a Pitken, a Koster or a Vehrs. . . . No; the writer is an anesthetist, and as such he recognizes that no single method of anesthesia can properly claim precedence and be used to the exclusion of the others."

There are an extensive bibliography and a name and cross reference subject index. The contents are made easily available by outlines under the headings of each chapter. There is considerable repetitious presentation of material in the book, but this is not objectionable, since each chapter is dealt with as a unit. It should be pointed out that if all those who administer spinal anesthetics had the knowledge contained in this book and understood how to apply it, spinal anesthesia would never fall into disrepute but would have an honored place in the practice of surgery until the advent of the perfect anesthetic.

Der Beginn der Lungentuberkulose beim Erwachsenen. Untersuchungen an 86 Reihen von Röntgenphotographien vom Gesunden bis zum Krankhaften uber Ursache, Gestalt, Entwicklungstempo, therapeutische Beeinflussbarkeit und Prognose der Erkrankung. Von Dr. H. Braeuning, Chefarzt der Fursorgestelle fur Lungenkranke in Stettin. Paper. Price, 22 marks. Pp. 222, with 177 illustrations and graphs. Leipzig: Georg Thieme, 1938.

This excellent monograph is printed on the best glazed paper and is well illustrated with roentgenograms and charts. There are a few minor typographic errors: some of the tables (for example, table 3) have duplication, figures do not total, and reference figures in the text are not exact. On page 180 for table 17 undoubtedly table 18 is meant. The use of flat plates also has the disadvantage of not locating lesions by third dimension and requires a careful regulation of the relationship of position of the x-ray tube to the position of each patient.

The work is the result of a study of 100,000 persons, of whom there were 80,000 roentgenograms from the various tuberculosis institutions of Stettin. Of this number only eighty-six cases were included in the report in which roentgenograms were taken in series of apparently well persons and the disease was observed from the inception as determined by the least possible changes on the roentgenograms. The periods from the last normal to the first one showing pathologic change varied from one month to one year. The important features of the course of the disease of each of these eighty-six patients is briefly recorded, accompanied by an excellent course chart of each and punctuated by well chosen roentgenograms of total or important lung regions. There are eighty-five of such reproductions. In this series the author's dictum of "anything can happen" is well shown, for there are many degrees of acuity and chronicity. Some cases presenting open infiltrates or other serious appearance heal spontaneously, others like them or of even better appearance may go on to a fatal issue even with treatment. The first appearance, therefore, is not always a good criterion of prognosis.

Fifteen per cent of the cases became open within the first year, 5 per cent more after the second year, 4 per cent more after the third, and 8 per cent more after the fourth. After twelve years 40 per cent were open. Three and five tenths per cent of the patients were dead after one year and 15 per cent after twelve years. Both of these figures are established on an average time of observation of about four years. Sixty per cent therefore became severely damaged for years, 40 per cent infectious and 15 per cent died. If they had been followed longer the results would perhaps be much higher. Judging by the author's earlier work, about 80 per cent of patients with open tuberculosis ultimately die of the disease, although this is subject to rigid interpretation of what constitutes an open lesion and also the kind and time of treatment. Truly, as the author states, tuberculosis in adults, for those who know its course, has not yet lost its terror. The blood picture is indefinite, as is the red cell sedimentation. Neither is specific. Practically all acute forms show changes of both, some chronic forms show changes of neither.

The high point of this work lies in the report on the early lesion from a roentgenologic standpoint with the collateral clinical observations.

The preponderance of lesions were infiltrates: twenty-six typical, thirty-four atypical or modified in some way, twelve having mixed flecks in cloudy infiltrates and others having fine flecks with or without linear fibrosis. They were located largely above the second rib: eighteen in the apex, six behind the clavicle, twenty in the first, five in the second intercostal space and one in the third. The others were widespread or irregular in position.

Other diseases could not be connected as causative factors in the beginning of tuberculosis. Grip and the acute onset of tuberculosis are quite similar and may be simultaneous or independent of each other. A differential diagnosis is suggested in the high sedimentation of grip in contrast to tuberculosis.

The author doubts whether pregnancy has any unfavorable effect on the course of beginning tuberculosis, but the figures are too few to justify conclusions. Most figures of pregnancy and tuberculosis are compiled on cases in which the disease is actually in progress.

In puberty there is a slight increase of unfavorable results in the group from 10 to 20 years of age over the adults (50 per cent to 34 per cent respectively), but most puberty cases show a youthful glow even in advanced disease.

The origin of the disease is assumed to be largely from exogenous reinfection. Only three cases were definitely proved to be from a primary focus of thirty-six definite primary lesions. Three others were from the hematogenous scattering of the primary, but the author prudently admits that many such cases may have been overlooked and grants that pathologic studies similar to those of Wurm may change the figures. Important argument in favor of exogenous reinfection, however, is that seven times as many nurses in tuberculous cases develop the disease as those working in welfare stations. This is of more significance since all their nurses reacted positively to tuberculin at the beginning of service.

This work comes near to the ideal "experiment" in the epidemiology of tuberculosis.

The 1938 Year Book of Physical Therapy. Edited by Richard Kovács, M D, Clinical Professor and Director of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Cloth. Price, $2.50. Pp. 486, with 131 illustrations. Chicago: Year Book Publishers, Inc., 1938.

This is the initial yearbook of physical therapy, aimed to serve the large body of medical men and their assistants in the use of physical energies in almost every field of medical practice. The editor states that he was attempting to meet "the constantly increasing, and in many respects spectacular, development of physical energies in the treatment of disease and injury during recent years." He says further that he wished to cover three main fields in physical therapy, namely (1) new developments in basic research and practical application, (2) the present status of clinical usage and (3) the types of treatments largely unknown in this country, in order to stimulate interest and

research along such lines as health resorts and spas, the use of natural therapeutic resources and climatotherapy, and physical education in the practice of medicine.

The book has two parts, one on the methods and apparatus of physical therapy, including some rather detailed accounts of the work of various investigators on the effects of physical methods, with some of the physiology and physics involved, and another on applied physical therapy in the treatment of a wide variety of physical conditions. The editor stressed the necessity of using physical therapy in conjunction with general medicine and surgery. In covering these fields, the literature referred to was limited to that of the preceding year, as is customary in yearbooks. In selecting articles from the foreign literature, the editor said that difficulty arose because of the lack of internationally accepted nomenclature, involving a problem which should be considered in future international congresses on physical therapy.

Dr. Kovács is the editor, yet it is sometimes uncertain which statements are his and which those of the investigators cited. Such objective comments are made as "the experiments proved that" and "the discussion is theoretical" and that certain experiments "have demonstrated." Yet comments signed by the editor are often placed in parenthesis and small print in the text, causing confusion as to which statements in the rest of the text are his and which those of the investigators cited.

On the whole the book represents a good start for a yearbook on physical therapy, and it will be valuable for its abstracts of recent literature.

Cardiovascular Disease in General Practice. By Terence East, M.A., D.M., F.R.C.P., Physician and Physician-in-Charge of Cardiological Department, King's College Hospital, London. Cloth. Price, 10s. 6d. Pp. 206, with 43 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

This book it intended to expound to the general practitioner those principles and practices which are of immediate utility to him in his everyday handling of cardiac patients. In this the author succeeds admirably. Function and etiology are emphasized in preference to morphology; this is in line with the modern trend in the field of cardiovascular diseases. The scope of the book can be appreciated by a glance at the chapter headings: interpretation of symptoms, physical examination, heart failure and its treatment, coronary circulatory failure, peripheral circulatory failure, rheumatic and syphilitic cardiovascular disease, chronic valvular diseases, subacute endocarditis, pericarditis, hypertension, arrhythmias, circulation in anemia, in lung and kidney disease, in anesthesia, in pregnancy and in athletes, congenital heart disease, diseases of the arteries and veins, the heart in older persons, and aberrations of the normal heart. The book avoids the undue emphasis on chronic valvular disease which has been so common in the past by covering the subject in three pages. The style approaches that used in compends in a tendency to outline the subject and to employ a staccato rhetoric. Proprietary drugs are stressed unduly and many of these are unfamiliar to the American reader. The insertion of brief bare outlines of case reports could well have been omitted. These are, however, minor criticisms, and the book is admirably suited for the audience intended, the general practitioner of some experience seeking to be brought in easy lessons abreast of progress in this field.

Essentials of Psychiatry. By George W. Henry, Associate Professor of Psychiatry, Cornell University Medical College, New York. Third edition. Cloth. Price, $5. Pp. 465. Baltimore: Williams & Wilkins Company, 1938.

Dr. Henry's excellent textbook has been considerably enlarged since its original appearance. Naturally the chapters dealing with the psychoses constitute the largest part. Borderline conditions cannot be dealt with in a book of this size. Perhaps more space is given to the topic of organic psychoses than is usually the case, but the matter is properly treated. The psychoneuroses are given a good deal of discussion. There is an excellent chapter on the method and purpose of mental examination, and a short but fairly good one on principles of treatment. Chapters on psychiatric nursing and psychopathology of the normal are included; those dealing with mental hygiene and disorders of childhood are perhaps too brief. Psychiatric social service work and the medicolegal aspects of psychiatry are touched on, and the final chapter deals with psychiatric history, a subject which perhaps is too sketchily dealt with here but is unfortunately almost entirely neglected in other textbooks. There is a brief bibliography. This is a good, simple textbook and is accurate enough for use in the earlier parts of a curriculum in psychiatry. It could be used as a basic text in a psychiatric course in a medical college provided it was supplemented in the later years by intensive reading in the literature of psychiatry. The work of Rosanoff is perhaps better suited to advanced students of psychiatry. No textbook of course can be entirely satisfactory, but this volume is subject to a minimum of criticism if one bears in mind that an attempt is made to cover a great deal of material in a limited space.

Outline of Roentgen Diagnosis: An Orientation in the Basic Principles of Diagnosis by the Roentgen Method. By Leo G. Rigler, B.S., M.B., M.D., Professor of Radiology, University of Minnesota, Minneapolis. Atlas edition. Cloth. Price, $6.50. Pp. 212, with 254 illustrations shown in 227 figures, presented in drawings and reproductions of roentgenograms. Figures 6 to 51 and 55 to 72 are drawings in an original technic by Jean E. Hirsch. Student's edition (exclusive of atlas). Paper. Price, $3. Pp. 212. Philadelphia, New York, Montreal & London: J. B. Lippincott Company, 1938.

This work appears in two editions: one with illustrations, and the other, a cheaper work, minus the plates but containing the same text. Essentially this is an outline of a teaching course in radiologic diagnosis and represents the considerable experience of the author. The book is divided into eleven sections, fairly well running the gamut of diseases to which the human body is subjected and in which the x-rays are used for diagnosis. The first section is devoted to an outline of general principles with brief descriptions of technics employed in roentgenology. Actual practical technic has been completely eliminated; only a solid residue of diagnostic facts is presented. Nevertheless a surprising amount of discussion is present. An interesting feature is the paragraph in the various sections which evaluates the particular usefulness of the roentgenogram in the locale or disorder involved. The plates in the complete edition are excellent and it is easy for the reader to grasp the salient points portrayed. There are a few line drawings of the more difficult portions of osteology and of the development of the ossification centers of the bones. For those physicians and students who seek guidance to methodical and clearcut interpretation of fluoroscopic and roentgenographic appearances, this small volume cannot be too highly recommended.

The Medical Dictator and Other Biographical Studies. By Major Greenwood, F.R.S., D.Sc., F.R.C.P. Cloth. Price, 7s. 6d. Pp. 213, with 6 illustrations. London: Williams & Norgate, Ltd., 1936.

The author of this book is listed as former statistician to the Lister Institute, chairman of the statistical committee of the Medical Research Council, president of the Royal Statistical Society and professor of epidemiology and vital statistics at the London School of Hygiene and Tropical Medicine. Naturally he has made the acquaintance of "men long dead and largely forgotten whose work has influenced the studies" he pursues, and he has inquired into what sort of people some of these dead investigators were. The subjects of his present inquiry are Galen, John Freind, "Heart" Latham, William Farr, Pierre Charles Alexandre Louis, Osler, and Arthur William Bacot. "Medical dictator" is an appellation which he may rightly bestow on Galen but which seems inappropriate to some, if not all, of the other personalities. Thirty-four pages of biography and criticism of an ancient whose system was based on the doctrine that all diseases depend on the balance or lack of balance of the four primary humors—blood, yellow bile, black bile and phlegm —seem too much.

Of Pierre Charles Alexandre Louis, the author says that his principal writings are unreadable. They are just sums. Louis apparently endeavored to establish a numerical system of diagnosis and prognosis, to the exposition of which he devoted a special memoir of sixty-five pages. When Osler in 1905 wished to lay a wreath on the tomb of Louis, no physician could be found in France who knew where he was buried.

Farr was a statistician and discovered a law to which his name has been attached and which "was the simplest possible

relation between the three ratios deducible from the four available figures which one could assume." He was able to foretell when the cattle plague which invaded England in 1865 would reach its maximum. After Farr retired, the British Medical Association officially expressed appreciation of his labor in behalf of statistical and sanitary science, of the light he had thrown on physiologic and pathologic problems and of the extraordinary services he had rendered in advancing the national health.

Latham had been a member of the staff of old St. Bartholomew's and a successful practitioner in London. He was also a critic of medical education. He believed that all knowledge was valuable but that, for a physician, the study of sick people was much more valuable than anything else.

John Freind is one of the heroes of the London College of Physicians. He became physician to the queen after the accession of George II. His "History of Physic" was his most important work and yet he made no important contribution to the art or science of physic. He had no use for ancient medical philosophy or modern medical systems, but he searched the literature for plain, practical remedies with no mystical nonsense about them. He died in 1728. The reason why Freind was beloved can be expressed in one word, character.

Cancer with Special Reference to Cancer of the Breast. By R. J. Behan, M.D., Dr. Med., F.A.C.S. Cloth. Price, $10. Pp. 844, with 168 illustrations. St. Louis: C. V. Mosby Company, 1938.

The author was formerly director of the cancer department of the Pittsburgh Skin and Cancer Foundation. Since he was unable to find in an abstracted form in a single monograph a description of the complex changes associated with the different phases of cancer, he began to collect, abstract, study and compile the principal facts and theories concerned with the etiology, diagnosis and treatment of cancer. The result was the present volume, which originally was written as a treatise on cancer of the breast. He reviews the advances in the study of cancer which seem to have substantial and positive foundations. He believes that our knowledge of the physiology and morphology of the cancer cell has about reached its limit of usefulness as a means of solving the cancer problem, that surgical intervention and irradiation have also reached the limits of their effectiveness, and that it is necessary for new methods of treatment to be developed from a study of the alterations in the biologic activity of the individual cancer cell. After a general consideration of the incidence and mortality of cancer in different countries and the relation of cancer to age and sex, he takes up the etiology, especially of cancer of the breast. Chapters followed on the pathology, symptomatology, diagnosis (including many so-called cancer tests), biopsy (including the technic), metastases and prognosis. Almost half of the book is given over to a consideration of the various forms of treatment. The author believes that the best results at present are obtained with a combination of surgical intervention and irradiation. In the treatment of cancer detailed consideration must always be given to the patient whose general state of health must be subjected to a critical investigation. The chapter on treatment is subdivided into sections on operative treatment, constitutional treatment and irradiation and includes a special section on the dosage of radioactive agents.

Air Conditioning: A Practical, Modern and Fundamental Treatise on the Subject of Air Conditioning, Air Distribution, Refrigeration, Comfort Cooling, Humidification and Air Purification. By Charles A. Fuller, M.E., Consulting Engineer on Air Conditioning, Heating and Ventilating, Electrical and Sanitary Equipment. With the collaboration of David Snow, Air Conditioning Engineer. Cloth. Price, $4. Pp. 577, with 300 illustrations. New York: Norman W. Henley Publishing Compnay, 1938.

This is a practical and fairly complete treatise on the mechanics of air conditioning. Written primarily for students, contractors and practical engineers, it contains much fundamental information to meet the needs of beginners in the art. There is little on physiologic and health aspects of air conditioning that would interest the physician. Whatever is said about the need of humidification, ionization or deodorization appears to have been based on manufacturers' literature. The print is large and readable and the illustrations are good. The index is fair and there is no bibliography despite the liberal use of basic sources of information.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Ethmoidal Sinusitis Attributed to Trauma.—The claimant, in the course of his employment, was struck on the forehead with a piece of metal pipe. A lacerated wound resulted, about 1½ inches long and extending down to the skull. A physician sutured the wound and treated it "in the usual way" for about six days. The published report does not show whether roentgenograms were made. According to the physician who treated the claimant at the time, the wound healed readily and there was no apparent reason why it should give trouble. Except for six days immediately following the accident, the injured workman lost no time from work until September 1936. In the interval, however, he had suffered from headaches of increasing intensity, which had become so severe as to prevent his working full time. The record shows that he was treated for "ethmoid sinus infection," but it does not show when that condition was first recognized or present any direct evidence concerning it. When the injured workman realized that he could no longer work full time—that is, two years after the accident—he filed a claim for compensation under the workmen's compensation act of Texas against his employer's insurance carrier.

The industrial accident board denied him compensation because he had not shown "good cause" for not filing his claim within six months after the injury. The claimant thereupon instituted suit in the district court, Wichita County, to set aside the order of the industrial accident board. Judgment was entered in his favor, and the insurer thereupon appealed to the court of civil appeals of Texas, Forth Worth.

The insurer contended that the claimant, as a matter of law, had not shown "good cause," as required by law, for his failure to file his claim within six months after he was injured. The appellate court pointed out, however, that the courts of Texas had often held that the question as to whether or not there was good cause for a claimant having failed to file his claim for compensation was a question of fact to be determined by a jury if one was demanded, and that the test was whether or not the claimant prosecuted his claim with such diligence as would have been exercised by a person of ordinary care under the same or similar circumstances. Quoting from *Texas Employers' Insurance Association* v. *Clark*, 23 S. W. (2d) 405, 408, the court said:

> That the employee did not believe his injuries to be serious would clearly afford a good cause for not giving notice and filing claim until it was learned they were serious. Compensation is not provided for pain and suffering, but for loss of wages, and there would arise no necessity for giving notice or filing a claim so long as the employee lost no time from his work, but believed his injuries were trivial.

The court could not properly have submitted to the jury an issue inquiring whether or not the claimant had shown good cause for not having sooner filed his claim; to have done so would have infringed the prerogative of the court. The court, however, submitted to the jury issues of fact on which the court might base its findings. The jury found that the claimant believed until about the time he filed his claim that the injuries would not disable him; that this belief prevented his filing his claim prior to the time when it was filed, and that a reasonably prudent person, situated as the claimant was, would have delayed the filing of his claim for a period as long as the claimant delayed in the present instance. The appellate court, therefore, refused to disturb the findings of the jury and of the trial court that good cause had been shown.

The insurer complained of the inadequacy of the testimony to support the finding of the jury that the claimant was totally and permanently incapacitated for work. The question, said the court, had to be determined from the opinions of experts among the medical profession, and it appeared to be as natural for them to disagree as it was for members of the legal profession. They seldom commit themselves to a positive statement that this or that injury to a part of the human anatomy will have a definite effect on the individual; they explain, and rightly so, said the court, that this is because of so many elements which

may enter into each case, such as infection, the physical condition of the person at the time of the injury, and many other like conditions The medical witnesses had testified, in effect, from hypothetical questions put to them that the claimant could not pass the physical examination necessary to enable him to accept employment in the oil fields such as he had formerly engaged in The physician treating the claimant for ethmoid sinus infection said that the blow on the claimant's head would probably produce such an infection, that in his opinion the claimant was incapacitated to do oil field work and that his incapacity was permanent To constitute total incapacity, it is not necessary to establish as a fact that the claimant cannot do any kind of labor, it is sufficient if he is disqualified from performing the usual tasks of a workman in such a way as to enable him to procure and retain employment There was ample evidence to support the finding of the jury favorable to the claimant

The appellate court accordingly affirmed the judgment of the trial court in favor of the claimant—*Texas Employers Ins Ass'n v Roberts (Texas), 116 S W (2d) 417*

Medical Practice Acts: Treatment of Physical Deformity by Cosmetologist Constitutes Practice of Medicine.—Three prosecutions were brought against Gardner, charging that he practiced medicine without having been licensed so to do From three judgments of conviction, he appealed to the court of criminal appeals of Texas Gardner admittedly had treated one Lato, the muscles about one of whose eyes had become stretched from the prolonged use of a loupe (a type of magnifying glass which fits over the eye), "causing the skin and flesh to sag down" Lato testified that he consulted Gardner concerning this condition Gardner put some "stuff" that smelled like chloroform around Lato's eye to kill the pain and then placed "a strong acid" around the eye, which burned the patient and caused such severe swelling as almost to close the eye Gardner continued to treat Lato for about four weeks and Lato paid him $75 for his services Gardner claimed that what he had done was not the practice of medicine but had been done pursuant to the practice of cosmetology, which he was licensed to practice He had used no chloroform nor acid, he said, but had applied only a "beauty peel," purchased by him in a drug-store

In the judgment of the court, Gardner's acts constituted the practice of medicine within the meaning of the medical practice act of Texas, which declares, among other things, that any person shall be regarded as practicing medicine who treats or offers to treat any physical deformity or injury, by any system or method, or offers to effect cures thereof and charges therefor The court affirmed the three judgments of conviction—*Gardner v State (Texas), 116 S W (2d) 402, Same, 116 S W (2d) 403, Same, 116 S W (2d) 403*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Digestive Diseases, Huntington, Ind.

5:777-850 (Feb.) 1939

Effect of Anterior Pituitary-like Hormone on Gastric Acidity in Man. H. Felson and L. Schiff, with technical assistance of Ellen S. Garber, Cincinnati.—p. 777.
*Observations on Incidence and Cause of Fever in Patients with Bleeding Peptic Ulcers. L. V. Dill and C. E. Isenhour, Nashville, Tenn.—p. 779.
Effect of Pyloric Obstruction on Filling and Emptying of the Gallbladder in Cholecystography. M. Feldman, Baltimore.—p. 785.
History and Development of Gastric Analysis Procedure (Second Instalment). F. Hollander and A. Penner, New York.—p. 786.
Disposable Nonbreakable Hard Enema Tip. M. Kraemer, Newark, N. J.—p. 791.
Attempt to Prevent Postoperative Jejunal Ulcer by Aluminum Hydroxide Therapy: Experimental Study in Mann-Williamson Dogs. G. B. Fauley, A. C. Ivy, L. Terry and W. B. Bradley, Chicago.—p. 792.
*Chronic Localized Gastric Purpura. R. Schindler, Chicago.—p. 796.
Review of Some Foreign Literature. R. Schindler, Chicago.—p. 799.
Problems of Maintaining Nutrition in the Highly Food-Sensitive Person. W. C. Alvarez, Rochester, Minn.—p. 801.
Peritonitis Due to Ruptured Acute Appendicitis in Children: Influence of Delay on Operative Mortality. R. Elman, St. Louis.—p. 804.
Pellagra Treated with Nicotinic Acid: Report of Ten Cases. V. H. Musick, Oklahoma City.—p. 807.
Studies on Water and Soap Enemas. R. D. Templeton and E. L. Borkon, Chicago.—p. 809.
Anorexia and Gastric Motility. Dorothy P. Gulliksen, Alma Fogelberg and L. Kardos, Chicago.—p. 814.

Fever in Peptic Ulcer.—Dill and Isenhour determined the incidence of fever (any rise in temperature above 99 F. which was sustained for more than two days, any rise to 99.2 F. or above for two days or any single rise exceeding 100 F.) in 199 male patients with proved peptic ulcers. Each patient had been observed in the hospital for more than three days and was known, within the limits of error, to have no intercurrent infection. The authors state that the incidence of fever in their patients (53 per cent) is identical with the series published by Bang but greatly exceeds those of Kroner (18 per cent) and Lorenz (24 per cent). They found that 80 per cent of their patients with bleeding ulcers were febrile. These figures do not differ greatly from those of Purjesz (73 per cent) or Bang (91 per cent) but are well above those quoted by Kroner (58 per cent). Their percentage of febrile, nonbleeding ulcer cases (46 per cent) is much higher than that of Kroner (16 per cent) or of Bang (7 per cent). Patients without demonstrable organic lesions had fever, according to the authors' definition, in a significantly high percentage (37.1). Their study shows that patients with ulcers have fever more frequently than patients with no demonstrable organic lesion and that bleeding increases this tendency. The presence of anemia also increases the febrile tendency in patients with both bleeding and nonbleeding ulcers. Massive and moderately severe hemorrhages are more frequently associated with fever than are small hemorrhages. The occurrence of fever could not be correlated with either the age of the patient or the duration of ulcer symptoms. The absence of leukocytosis in the patients led the authors to assume that infection of the base of the ulcer or an associated gastritis or duodenitis is not important in the production of fever. Experimental evidence seems to indicate that little part is played in the production of fever by either blood in the intestinal tract or absorption of blood degradation products. There was relatively high incidence of fever in patients with gastric neuroses.

Chronic Localized Gastric Purpura.—Schindler believes that chronic localized purpura of the stomach is not only a new but also an important disease. Gastroscopically, besides the more or less numerous mucosal hemorrhages, dark brown round or star-shaped spots may be found. They are usually from 2 to 5 mm. in diameter but occasionally much larger. They apparently develop from the mucosal hemorrhages; the transition may be observed if the patient is examined with the gastroscope at frequent intervals. Hemorrhages and pigment spots may be found along the anterior and posterior wall but are most frequently in rows along the lesser curvature. The common site of their location is a point about 3 cm. above the angulus. The pigment spots disappear slowly, probably by absorption. However, some hemorrhages, instead of being absorbed, become ulcerated and develop into a hemorrhagic erosion, red, grayish red or brownish red. Gastroscopy has verified the observation that true hemorrhagic erosions do exist. By the fact that they may become ulcerated, the eruptions of the localized purpura of the stomach are definitely different from the cutaneous eruptions in generalized purpura. This difference is easily explained. In the stomach the acid gastric juice developing peptic power is present, in which case the gastric wall may lose its autoprotective power against autodigestion if it is damaged for a long time by some disturbance of the circulation. The frequent coincidence of such isolated gastric purpura with true gastroduodenal ulcer does not prove that hemorrhagic erosion is the acute stage of chronic gastroduodenal ulcer. Chronic inflammation in stomachs containing true gastroduodenal ulcer is apparently secondary to the ulcer. However, the presence of noninflammatory gastric hemorrhages is not easily explained by assuming that they are effected by the ulcer, it would be difficult to explain why they are so often found at the place of predilection of ulcers (the angulus), and finally the author believes that he has observed the transition of mucosal gastric hemorrhages into true gastric ulcer. Therefore his opinion is that (1) there is a definite relationship between chronic localized gastric purpura and chronic gastroduodenal ulcer, (2) chronic isolated gastric purpura may precede or follow chronic gastroduodenal ulcer or they may be found together and (3) the hemorrhagic erosion, having its origin from the chronic localized gastric purpura by the peptic quality of the gastric contents, may be the acute stage of chronic gastroduodenal ulcer.

Cancer in the Navy.—Peller and Stephenson deal with a study of the cancers that occurred in the United States Navy during the years 1929 to December 1936. During this period there were 320 deaths from cancer. Of these, ninety-eight men were in active duty status, in seventeen additional persons the onset of the malignant condition was during active service but they died following discharge from the navy and 205 of these cases occurred in men in an inactive duty status. Compared to civil populations there are many more surface cancers in the navy personnel and fewer internal cancers. Since the former are easily cured, the average case fatality of all cancers (about 50 per cent) is low. Owing to the greater frequency of cuta-

neous cancers and lesser frequency of internal ones, the mortality between the ages from 25 to 64 is about 50 per cent lower than would be expected from age, sex and color-specific cancer rates of New York for 1930. The cutaneous and lip cancer morbidity among active navy personnel is several times as high as in the civil population. This is explained by greater exposure to cutaneous irritants, especially sun, salt water and wind. Since total morbidity in the active personnel and total mortality in the ages above 65 are not higher than in the civil population, the conclusion seems to be justified that increased exposure to the sun is beneficial rather than detrimental.

Specific Treatment of Type I Pneumonia.—Finland and Brown state that the death rate among cases of type I pneumococcus pneumonia treated with concentrated type specific antibody at the Boston City Hospital has been regularly one half or less that of similar contemporaneous cases not treated with serum. This has remained true in recent years in spite of the fact that the proportion of cases treated with serum has increased from 43 to 89 per cent. In the cases treated with serum before the end of the fourth day of illness the death rate is less than one third of that which occurs in cases not treated with serum. Bacteremic and nonbacteremic cases are equally influenced. The greatest reduction in the death rate occurs in patients less than 50 years of age, but those of other age groups are probably also beneficially affected by serum treatment. Empyema occurred after serum treatment chiefly in bacteremic patients, and its frequency was proportional to the delay in beginning treatment. Type I antipneumococcus serums produced in both horses and rabbits were potent and effective. There are insufficient data to indicate any superiority of the one over the other. Sulfanilamide in the small number of cases in which it was used alone or with serum influenced the course of type I pneumonia only slightly if at all.

Ascorbic Acid in Plasma in Achlorhydria.—In order to obtain further information on the concentration of ascorbic acid in the blood of patients with achlorhydria, Alt and his co-workers determined the ascorbic acid of the blood plasma in forty-four cases of achlorhydria associated with pernicious or iron deficiency anemia. The results in general seem to confirm the hypothesis that a relationship exists between achlorhydria and vitamin C deficiency. With diets adequate in vitamin C, the mean blood ascorbic acid was significantly decreased from the normal in the cases of pernicious anemia but not in the iron deficiency anemia group. With diets inadequate in vitamin C the plasma ascorbic acid was significantly decreased from that observed in twenty-four controls, in both the pernicious and the iron deficiency anemia groups. The plasma ascorbic acid values showed no correlation with the erythrocyte counts and hemoglobins. Experiments were performed in an attempt to explain why there might be an association between vitamin C deficiency and achlorhydria, but none established an explanation for such an association. Possibly a combination of such factors as lack of an acid gastric juice, bacterial growth and malabsorption might be sufficient to interfere with the assimilation of ascorbic acid in such cases.

Active Virus of Human Influenza.—Morrison and his associates studied the effect of active human influenza virus on the complement fixing antibodies of the serums of patients vaccinated with it. They compared this with a similar and simultaneous study of the serums of a group of nonvaccinated controls. The serums of the same individuals were studied over a period of from one to two years under similar environmental conditions but in the presence of a variety of intercurrent respiratory infections. Constantly low titers of complement fixing antibodies were found in the same individual over a long period if no infection with influenza virus had occurred and even though they had suffered from other types of respiratory infection. Such low titers persisted among the hospital personnel in a large urban center as well as in the more isolated sections studied. Repeated vaccination with chick embryo tissue culture vaccine as prepared in large batches for injection did not affect the complement fixing antibodies. If the complement fixing antigen is a soluble substance liberated during multiplication of the virus in the tissues it is also possible that the use of infected mouse lung rather than chick embryo tissue culture vaccine might result in an increase in the complement fixing antibodies. Vaccine derived from chick embryo tissue cultures following parenteral injection produced characteristic increases in the neutralizing properties of serums. By the same route, in mice, it also produced immunity to the virus injected as well as cross immunity to other strains of human influenza virus. In a few instances marked elevation in titer of complement fixing antibodies studied in the serums of individuals following hospitalization established the cause of their respiratory infections as epidemic influenza. Such increases were absent following other types of respiratory infection. By such studies future epidemics of respiratory disease may be more satisfactorily classified as to etiology.

Fatal Cases of Acute Manic-Depressive Psychosis. C. P. Larson, Tacoma, Wash.—p. 971.

Paucity of Arthritis in Psychosis.—Gregg presents the morbidity rates of arthritis in Massachusetts and among psychotic persons in the Massachusetts state hospitals. It has been stated that approximately 145,000 individuals in Massachusetts suffer from rheumatism. A similar prevalence among psychotic persons does not coincide with the author's experience or with the opinions of other hospital superintendents whom he consulted. To obtain more definite information, he sent a ques-

tionnaire to hospital superintendents, and from the first eight state hospitals and from one United States Veterans' hospital in Massachusetts the reports gave four bedridden and sixteen seriously handicapped patients with arthritis among more than 15,000 patients in these nine hospitals Two of these twenty patients were less than 40 years of age and in eight of the remaining eighteen arthritis developed before entrance to the hospital Whether this means that the arthritis antedated the psychosis is unknown Assuming that the data are comparable, the incidence of disabling arthritis is seventeen times greater in the community than among psychotic patients in Massachusetts state hospitals Evidence obtained by other investigators that confirms the discrepancy of the incidence of arthritis in the two groups is presented Among psychotic patients without a prolonged stimulus-reaction span, because of impaired imagination and memory, there is little prolonged muscle tension or drag on the joints, little setting of the stage for prolonged ischemia, malnutrition or infection of the joints and therefore seldom chronic arthritis

Body Build Differences in Epilepsy.—In order to determine whether differences exist in body habitus of deteriorated and nondeteriorated epileptic patients, Paskind and Brown took anthropometric measurements of fifty deteriorated and thirty-nine nondeteriorated epileptic patients Eighty measurements were recorded for each patient according to the technic described by Martin, Saller and Draper Fifty-seven indexes were also calculated for each patient to show the relation in size existing between a given part of the body and other parts With few exceptions the mean values for the various measurements are greater in the deteriorated patients Significant differences also exist in the mean values of the indexes All indexes relating weight to height indicate that the deteriorated patients are heavier per unit of height and that their trunks are wider and deeper per unit of height than are those of the nondeteriorated patients The deteriorated patients have narrower faces per unit of face height than do the nondeteriorated ones Trunk and entire body measurements and indexes of exceptional size (large or small) occur more frequently in the nondeteriorated patients, whereas values of unusual size in head, hand and foot measurements and indexes occur more often in the deteriorated patients

End Results in Radiation Therapy of Cancer of Cervix—Stevens and Payne present statistics on 293 cases of carcinoma of the cervix, 223 of which were treated by radiation therapy prior to 1933 In the 223 cases there were nine of carcinoma of the cervical stump after supracervical amputation for fibroid tumor Five of these were proved by biopsy to be squamous cell carcinomas All patients as they came were accepted for treatment In about 75 per cent the cancers were far advanced Of the 223 cases, 137 were proved by biopsy and 20 4 per cent of these were cured for five years or more Of the 177 traced cases comprising both those histologically proved and those only clinically diagnosed, the number of five year cures is identical with that of the cases proved by biopsy. The cancers of eleven patients were cauterized by the Percy soldering iron or by electrocautery previous to irradiation They did not live through the five year period Panhysterectomies on fourteen patients with early operable cancers were performed at varying intervals before radiation treatment Three of these, microscopically proved, lived beyond the five year period, two for nine years and one for sixteen years Two patients with squamous cell carcinoma, each 28 years of age, who had radiation treatment alone survived the five year period, one for seven years Twenty-three patients whose cancers were proved by biopsy recently traced are alive, well and clinically cured after from five to sixteen years Of the total number of cases in this survey, 52 4 per cent had roentgen and radium therapy, 42 2 per cent had roentgen therapy without radium and 4 4 per cent had radium without roentgen therapy None of the ten patients treated with radium alone survived the five year period Nearly all the cases in this series should, the authors say, be classed as stage 3, and efficient roentgen irradiation throughout the entire pelvis should have been administered in all of them Radium irradiation was inadequate

Treatment of Severed Tendons and Nerves of Lower Arm—O'Shea presents the data on the 870 severed tendons and fifty-seven severed nerves of the hand, wrist and forearm that were treated by the surgeons of St Vincent's Hospital during the last fifteen years He states in conclusion that primary repair of tendons should be performed whenever possible The interval between injury and operation should be short The simple mattress stitch (black silk) will approximate the tendon ends and destroy fewer lymph channels Only the long flexor tendon—the profundus—should be repaired Repaired wounds should never be drained If drainage is necessary, primary repair should not be performed Infection occurred in 40 per cent of drained wounds Infection occurred almost twice as frequently at the wrist as on any surface of any digit It occurred in 15 per cent of all operations but in less than 3 per cent of 101 wounds that were not drained but repaired with black silk sutures, as compared to 18 per cent of 130 nondrained wounds repaired with chromic catgut "Full thickness" skin

grafting should be performed as soon as possible when the skin over tendons or nerves is evulsed. The use of black silk permits early motion because of its increased tensile strength and fewer edematous reactions. A patient should be hospitalized for at least two weeks and in bed for the first week giving maximal rest to the hand. The hand should be elevated for several days. The "end results" of tendon repair were impaired and retarded by fractures (ninety-five) and severed nerves which necessitated prolonged immobilization in splints. The end result is greatly dependent on the surgeon's personal management during the first three or four weeks of postoperative care. A follow-up of 40 per cent of the repaired tendon cases shows satisfactory functional results in 80.5 per cent of the cases. All extensor tendons showed 94 per cent satisfactory results, the flexor tendons of the wrist 81 per cent and the digital flexor tendons only 65 per cent. A partially severed nerve should be repaired in order to prevent the formation of scar tissue, which hinders regeneration of the nerve fibers. A follow-up of 40 per cent of the repaired severed nerves showed satisfactory functional results in 77 per cent of the cases. Satisfactory regeneration was obtained in 70 per cent of the ulnar, 78 per cent of the median and 100 per cent of the superficial branch of the radial nerve injuries. Motor function is difficult of restoration in lacerations of the ulnar nerve above the wrist. No deaths occurred in any of the 311 operative cases of tendon or nerve injuries.

Insulin and Collapse Therapy in Diabetes Complicated by Tuberculosis.—Elwood gives the results of collapse therapy for pulmonary tuberculosis and the use of the newer insulins for the control of concomitant diabetes in twenty-one cases. Despite the limitations imposed on the successful continuance of artificial pneumothorax, the employment of this type of therapy restored more than three times as many to health as did elected or enforced rest. The percentage of effective pneumothorax obtained parallels the results observed in nondiabetic persons. Protamine zinc insulin utilized in all stages of both diseases was as applicable as insulin. It revealed limited advantages over insulin in the progressive phases of tuberculosis, greater adaptability and better management in tuberculosis therapeutically controlled or regressing. It is of greatest use in diabetes and arrested pulmonary tuberculosis and its advantages in these cases over insulin are comparable to those noted in otherwise uncomplicated diabetes. In terminal pulmonary disease it has little or no advantage over insulin in the control of the diabetic derangement.

Extrapulmonary Tuberculous Complications.—In an analysis of 1,116 postmortem examinations of patients dying of pulmonary tuberculosis, Perla and Biller found that laryngeal involvement occurred in about one third of the cases. Tuberculous enteritis complicated pulmonary tuberculosis in more than half of the cases. In cases of tuberculosis of the larynx, tuberculosis of the intestine generally develops. The epididymis was practically never involved without the presence of a tuberculous focus in the prostate. Tuberculosis of the genital tract is a ready source for further hematogenous dissemination. Gross renal tuberculosis was absent in more than 90 per cent of the 1,116 cases. In general, involvement of the larynx and intestine occurs in active progressive diseases of the lungs, but renal and genital tuberculosis are associated with fibrotic pulmonary lesions or hematogenous pulmonary tuberculosis. Amyloid disease is particularly prone to develop in tuberculous patients with extensive extrapulmonary complications.

Dermatitis After Sulfanilamide Therapy.—During the last fifteen months Tedder encountered fourteen cases of sulfanilamide dermatitis. Six patients were cooperative enough to permit thorough study. The individual cutaneous lesions due to sulfanilamide were of three general types: (1) the maculopapular or morbilliform eruptions of rather limited distribution, precipitated or aggravated by exposure to sunlight, (2) widely distributed lesions ranging from macules and papules to edema and urticaria-like wheal formations, with occasional coalescence of the individual lesions, and (3) purpuric eruptions. Purpuric eruptions followed prolonged medication in one case; they did not appear until the third week of treatment. The history did not definitely reveal whether dermatitis had preceded the purpura; however, examination showed many fine macular lesions associated with multiple purpuric lesions. These were chiefly on the dependent portions of the body. There was no evidence of similar lesions of the internal organs. There were several cases of a maculopapular eruption with multiple small unruptured vesicles, limited to the areas exposed to sunlight. This disappeared when the drug was stopped. Three patients agreed to resume modified sulfanilamide therapy after ten days. There was no recurrence of the eruption. The patients were advised to avoid exposure to sunlight. After five days, suberythema doses of ultraviolet radiation were given to previously uninvolved areas of two patients. The dermatitis did not recur. The same amount of ultraviolet radiation precipitated a generalized eruption in the third case. This eruption again responded to elimination of the sulfanilamide, probably indicating that the patient became sensitized to the drug.

Jaundice and Syphilis.—Lane points out that from 1929 to 1935 there have been 100 (among 3,186 new cases of syphilis) cases of jaundice at the dermatosyphilologic clinic of the Massachusetts General Hospital. Arsphenamine was injected 51,241 times at the hospital, showing that jaundice occurred in 3.2 per cent of the cases of syphilis and after 0.2 per cent of the injections. Eleven of the cases of the disease were of congenital origin, nine primary, twenty-five secondary and fifty-five late. The central nervous system was involved in fourteen cases. In only eleven cases was jaundice present longer than eight weeks. In three cases jaundice occurred twice during treatment and in four it lasted for fifteen or sixteen weeks. The latter group comprised cases of late disease treated with a bismuth preparation interrupted by the jaundice. In none were more than ten injections of neoarsphenamine and twenty-two of the bismuth preparation given. The large number of cases of jaundice in which comparatively few injections of arsphenamine are given, as well as the large number of cases of syphilis in which much more arsphenamine produces no jaundice, would argue against arsphenamine as the main factor. It does not seem probable that arsphenamine is the only cause or even the chief cause. The occurrence of jaundice in so many cases of the present series in which bismuth compounds were used brings up the question of bismuth as a partial cause. If the bismuth is activated by liver extract and some slight damage is done by arsphenamine or by syphilis or by both, the bismuth may be the precipitating factor in breaking down certain of the hepatic functions and producing jaundice. The effect of multiple factors is difficult to estimate, but it seems clear that more than one causal agent is at work. Neither arsenic nor syphilis can account for the jaundice in all cases or even in a large majority. In general, in the treatment of this form of jaundice the administration of saline laxatives, forcing of liquids, bed rest and a high carbohydrate and low fat diet have been prescribed. Intravenous use of calcium preparations may be of help. With regard to the continuation of antisyphilitic treatment, it is the author's opinion that in the early stages of syphilis or in the presence of active syphilitic lesions the use of arsphenamine, perhaps in slightly reduced doses, of a bismuth preparation and perhaps of potassium iodide is justified. The clinical picture in the individual case must be the guide. In late and inactive congenital disease active treatment should be omitted until the jaundice has disappeared for several weeks and then resumed, perhaps with a bismuth compound at first. In the cases in which jaundice appears some time after treatment has been stopped, hepatorecurrence should be suspected and the patient given a bismuth compound or mercury and iodide rather than arsenic at this time.
